Deaths Exceeded Births in Nearly Half of U.S. Counties Last Year

Kenneth M. Johnson

Even before the onset of the SARS-CoV-2 pandemic, deaths were at a record high in the United States last year (2,835,000), but there were the fewest births (3,792,000) since 1986, according to new Census Bureau estimates. Between July 2018 and July 2019, the surplus of births over deaths (957,000) was the least in more than 50 years. Because of this smaller surplus and diminished immigration, the U.S. population grew by just 0.48 percent last year—the lowest population growth rate since 1919. With more deaths and fewer births, more people died than were born last year in 1,430 of the 3,142 U.S. counties (46 percent). The extent of this natural decrease (when deaths exceed births) is increasing. Ten years ago, just 889 counties (28 percent) had more deaths than births. Once natural decrease occurs, it is likely to reoccur. Between 2010 and 2019, 20 percent of counties had natural decrease every year, 19 percent in 1 to 4 years, and 23 percent in 5 to 8 years. Only 39 percent of all counties had more births than deaths in every year.

Natural decrease occurs more in rural than urban areas. It is widespread in agriculture, mining, timber processing, and older industrial regions. Natural decrease is more common in counties with larger proportions of older adults, fewer women of child-bearing age, and low fertility rates. Since the Great Recession, fertility has diminished the most among younger women and it is unclear whether these births are being delayed or will be foregone. This has significant implications for the future incidence of natural decrease, as does the rapidly unfolding SARS-CoV-2 pandemic.

In the United States, fewer births and more deaths reduced population growth to a 100-year low. In nearly 46 percent of counties, more people died than were born last year.
