DEVELOPMENT OF GENOMIC RESOURCES

AND

IDENTIFICATION OF MARKER-TRAIT ASSOCIATIONS

IN STRAWBERRY

BY

LISE L. (BOUCHARD) MAHONEY

Bachelor of Science, University of New Hampshire, 1976 Master of Science, University of New Hampshire, 2008

DISSERTATION

Submitted to the University of New Hampshire in Partial Fulfillment of the Requirements for the Degree of

> Doctoral of Philosophy in Plant Biology

> > December, 2014

This dissertation has been examined and approved in partial fulfillment of the requirements for the degree of Doctor of Philosophy in Plant Biology by:

Dissertation Director, Thomas M. Davis Professor of Biological Sciences

James E. Pollard Professor Emeritus of Plant Biology

James Brent Loy Professor Emeritus of Biological Sciences

Rebecca G. Sideman Full Extension State Specialist/Professor of Food and Agriculture

Joanne Curran-Celentano Professor of Molecular, Cellular, and Biomedical Sciences

On October 10, 2014

Original approval signatures are on file with the University of New Hampshire Graduate School.

DEDICATION

I dedicate my dissertation to my husband, Peter Myles Mahoney, family and friends who encouraged me every step of the way and which have made it possible for me to successfully complete this project.

ACKNOWLEDGEMENTS

This investigation was made possible through the financial support of the following: the UNH Department of Biological Sciences, the New Hampshire Agricultural Experiment Station, the UNH Graduate School Summer TA Fellowship program, the USDA Specialty Crop Research Initiative Grant 2009-51181-05808, "*RosBREED: Enabling Marker-Assisted Breeding in Rosaceae*"; and the Anna and Raymond Tuttle Environmental Horticulture Fund. In addition, *Fragaria iinumae* genomic resource development and genotyping was funded in part by a consortium consisting of: Thomas M. Davis, UNH; James Hancock, Michigan State University, Kevin Folta, University of Florida; Judson Ward, Driscoll Strawberry Associates; and Dan Sargent, Fondazione Edmund Mach, Research and Innovation Centre, San Michele all'Adige, Italy. Finally, research reported in the verticillium wilt chapter (Scientific Contribution Number 2530 from the New Hampshire Agricultural Experiment Station) was in part funded by a grant from the USDA National Germplasm System (Small Fruits) award #358-2100-038-01S, *Screening for Verticillium Wilt Resistance in Wild Diploid and Octoploid Strawberry Germplasm*.

I wish to thank my advisor and committee for their support and valuable critics in the course of this project. Particularly, I want to thank my advisor Thomas M. Davis for his thorough edit of my dissertation. I want to thank Brent Loy for his encouragement and ideas towards development and release of new strawberry hybrids. I want to thank Joanne Curran-Celentano for her generosity in the use of her lab and equipment. I want to thank Becky Sideman for her insights on cultural practices related to strawberry. And finally, I want to thank Jim Pollard for his encouragements and belief in my abilities.

In addition, I want to thank John McLean and the staff at the Woodman Farm for their continual maintenance of the strawberry fields and David Goudreault and staff at the McFarlane Greenhouses for their continual maintenance of the strawberry plants.

I wish to thank my family and friends, who have patiently encouraged me during this project. And, finally, I wish to acknowledge my husband, Peter Myles Mahoney, who has held up the home front and without whose support I would not have been able to complete my dissertation.

ABSTRACT

DEVELOPMENT OF GENOMIC RESOURCES AND IDENTIFICATION OF MARKER-TRAIT ASSOCIATIONS IN STRAWBERRY

BY

LISE L. (BOUCHARD) MAHONEY

University of New Hampshire, December, 2014

Crosses were performed and progeny populations were developed in diploid and octoploid strawberry (*Fragaria*) species for the purposes of genetic analysis and breeding. A high throughput genotyping platform – the Affymetrix IStraw90® Axiom® strawberry SNP array – was evaluated and employed for these purposes. Phenotyping was conducted with respect to several traits of interest, including flower color, flower and fruit pigment compositions, and verticillium wilt resistance, for the ultimate purpose of identifying marker-trait associations useful in breeding.

In the ancestral diploid species *Fragaria iinumae*, an F2 mapping population was developed from a cross between two accessions previously collected in Hokkaido, Japan. High-throughput genotyping platforms, the IStraw90 SNP Array and Genotyping-by-Sequencing (GBS), were utilized to develop high density linkage maps for *F. iinumae*. A linkage map based on 21 of the F2 generation plants genotyped on both platforms consists of 4,110 markers, while the second map based 85 F2 plants genotyped on only GBS consists of 895 markers. The linkage

maps will used in a parallel research project to anchor an *F. iinumae* genomic sequence assembly, with the aim of providing an additional reference genome for *Fragaria*.

A 455 member Closed Pedigree Set of octoploid strawberry plants was developed with diverse flower colors and progress was made on improvement of fruit quality through selection. The range of floral cyanidin and pelargonidin contents determined by HPLC in the progeny exceeded the range of contents of the founding parents, and thus exhibited transgressive segregation. The non-white (NW) flower trait was found to be a completely dominant to white, and no true-breeding, non-white flowered plants were found. The IStraw90 SNP Array was utilized to genotype 41 members of the Closed Pedigree Set and among a total of 5,674 segregating markers, 35 markers predictive of NW flower color were identified on chromosome 5. Additional genotyping will be required to further characterize the marker-trait association for color and to identify quantitative trait loci for hue.

Fragaria diploid and polyploid species were phenotyped for verticillium wilt resistance, and disease resistance ratings of the octoploid cultivars were compared to the results of previous published studies and presented in a pedigree format to help identify sources of resistance. The results will be used to identify germplasm for developing populations for high throughput genotyping on the IStraw90 Array for the ultimate goal of identifying marker-trait associations for the purpose of marker-assisted breeding for resistance.

INTRODUCTION

Strawberry is an important crop

Strawberry is an important crop in the United States valued at over \$2.9 billion per year. Annual production has increased steadily to the current level of 3.0 billion pounds from a mere 500 million pounds in 1970 (ERS-USDA 2012). New Hampshire produces slightly over one million pounds of strawberries per year, valued at \$2 million (Schloemann 2006). Assuming NH residents are typical consumers of strawberry, at the current nationwide strawberry per capita consumption of 9.0 pounds a year (ERS-USDA 2012), and a NH population of 1.3 million people (Gallager 2011), NH consumes an estimated 11.7 million pounds of strawberries annually. In sharp contrast, NH is only producing 1 million pounds (Schloemann 2006) of strawberries a year, indicating that demand far exceeds local production. The presence of a strong ornamental industry, which is the single largest agricultural sector in NH, also highlights an opportunity for developing locally adapted ornamental cultivars targeting homeowners and landscapers, and a broader extended season for consumption of locally grown strawberries.

Public strawberry breeding programs in the USA

In the United States, public strawberry breeding programs exist at six locations: University of California, Davis; University of Florida; NC State University; USDA Beltsville Maryland; Cornell University; and Oregon State University. In the northeastern U.S. and Canada, the only strawberry breeding programs are those at Cornell University and the Nova Scotia Kentville Research Station. The strong genotype \times environment interaction observed in strawberry cultivars points to the need for locally developed varieties (Hokanson et al. 2000). A breeding program in New Hampshire will provide specialty growers, small farms, and a strong ornamental industry with cultivars selected in and suited for our environment. These locally adapted cultivars should also be well-suited for other New England states including Maine, Vermont, and Massachusetts, which have similar agricultural settings and climates.

Strawberry germplasm

Fragaria is part of the economically important Rosaceae family. This family includes fruit- or nut-bearing members such as *Malus* Mill. (apple), *Prunus* L. (almond, apricot), and *Rubus* L. (raspberry), and ornamentals such as *Potentilla* L. (cinquefoil) (Judd et al. 2002). The *Fragaria* genus has a basic chromosomes number of x=7, and is represented by twelve diploid species, five tetraploid species, one hexaploid species, three decaploid species, and three octoploid species (Hummer et al. 2011, Hummer 2012).

Diploid strawberry - There are currently twelve recognized diploid strawberry species (Hummer et al. 2011), including *F. vesca*, *F. bucharica*, *F. chinensis*, *F. viridis*, *F. iinumae*, *F. nilgerrensis*, *F. daltoniana*, *F. nubicola*, *F. mandshurica*, *F. nipponica*, *F. pentaphylla*, and *F. ×bifera* (Hancock et al. 1993, Hummer et al. 2011). *Fragaria vesca* is found from the northern part of British Columbia, across North America, and south to Central America in San Salvador (Staudt 1999), on the island of Hawaii (Hancock et al. 1993), and in Europe (Hancock et al. 1993). *Fragaria vesca* is represented in the Americas by subspecies *americana*, *bracteata*, and *californica* (Darrow 1966), and by *subspecies vesca* from Europe to Siberia (Folta et al. 2006). *F. ×bifera* is found in France and Germany. *F. viridis* ranges from Europe to western Eurasia. The remaining nine species are found in the Far East. Most of the diploid species are

red-fruited, but there are a number of exceptions including white-fruited forms of *F. nilgerrensis* ssp. *nilgerrensis*, white-to-pink *F. daltoniana*, white-fruited *F. pentaphylla* (Hummer et al. 2011) and a few *F. vesca* ssp. *semperflorens* varieties *that* have yellow fruit (Darrow 1966).

Diploid ancestors of *F. vesca* and *F. iinumae*, and possibly a third as-yet-to-be-identified diploid are considered to be ancestral to the octoploid strawberry (Hancock 1999, Folta et al. 2006, Davis et al. 2007, DiMeglio et al. 2014). The only current reference sequence for strawberry is based on yellow-fruited *F. vesca* ssp. *semperflorens* 'Hawaii 4' (Shulaev et al. 2011).

<u>Tetraploid strawberry</u> - There are currently five recognized tetraploid strawberry species. All are found in the Far East and include *F. corymbosa*, *F. gracilis*, *F. moupinensis*, *F. orientalis*, and *F. tibetica* (Hummer et al. 2011). The tetraploids are typically red-fruited, but *F. tibetica* f. *alba* is white-fruited (Hummer et al. 2011).

<u>Hexaploid strawberry</u> - There is only one recognized hexaploid strawberry, *F. moschata*, indigenous to Europe and Siberia (Hummer et al. 2011), and it has red fruit.

<u>Decaploid strawberry</u> – There are three recognized decaploid strawberry species, *F. iturupensis* found on the Iturup Island, *F. cascadensis* found in the North American cascades, and *F. ×vescana* cultivated in Europe (Hummer et al. 2011, Hummer 2012). All three of these decaploid species are red-fruited.

<u>Octoploid strawberry</u> - There are three recognized octoploid species, *F. chiloensis*, *F. virginiana*, and *F. ×ananassa* (Hummer et al. 2011).

F. chiloensis is found on the west coast of North America (Alaska to California) and South America (Ecuador, Peru, and Chile), and in Hawaii. *F. chiloensis* also grows at high altitudes in South America in areas where it has been under cultivation for many years, as early as 1,500 (Darrow 1966). *Fragaria chiloensis* is represented by four subspecies: *lucida* and *pacifica*, which are red-fruited and found in North America, and *F. chiloensis* f. *chiloensis* (white fruited) and f. *patagonica* (red-fruited) found in Central and South America (Staudt 1999).

Fragaria virginiana grows wild throughout North America including Canada and the United States from Alaska to Mississippi (Staudt 1999). *F. virginiana* is represented by four subspecies *virginiana*, *glauca*, *grayana*, and *platypetala* (Staudt 1999). All of the subspecies have red fruit with white to red internal color (Staudt 1999).

F. ×*ananassa* arose in a French garden from an accidental hybridization in the 1700's between a white-fruited Chilean strawberry *F. chiloensis* ssp. *chiloensis* and a wild North American species, *F. virginiana*. (Darrow 1966). The considerable diversity exists within both *F. chiloensis* and *F. virginiana* wild species (Hancock et al. 2000) offer a rich germplasm pool for breeding (Hancock et al. 1993, Hancock et al. 1993, Hancock et al. 2010, Stegmeir et al. 2010). Both the white- and red-fruited forms of the South American *F. chiloensis* have been used in breeding, and cultigens of the white-fruited *F. chiloensis* are grown and marketed in Chile (Hancock et al. 2001, Carrasco et al. 2007). The white-fruited forms of *F. chiloensis* contain only trace levels of anthocyanins (Saud et al. 2009), although the achenes are red, while the red-fruited form lacks the high cyanidin trait of particular interest to my research. In contrast, I have identified in a certain North American *F. chiloensis* germplasm accession exceptionally high fruit cyanidin content (Mahoney, 2007; Mahoney et al., 2009a).

The genome of strawberry

The *F*. ×*ananassa* genome (2n=8*x*=56) has a 1C genome size of 780-800 million base pairs (Mbp) (Davis et al. 2007). The complexities of octoploidy provide a challenge for genetic analysis, thereby drawing attention to the ancestral diploid species, *F. vesca* and *F. iinumae* (Davis et al. 2009, Mahoney et al. 2009) as research models. Diploid, *F. vesca* 'Hawaii 4' (2n=2x=14), the reference genome for strawberry (Shulaev et al. 2011) has a 1C genome size of ~240 Mbp. 'Hawaii 4' shares a high degree of microsynteny with *F. ×ananassa* (Sargent et al. 2009).

The majority of strawberry cultivars on the market are *Fragaria* × *ananassa*. The few exceptions are European diploid *F. vesca* 'Alpine' varieties, including 'Yellow Wonder', and 'Baron Solemacher'. Most *F.* × *ananassa* cultivars have been derived from continual breeding and hybridizations of the original cross of *F. chiloensis* and *F. virginiana* (Darrow 1966) with some introgression from wild octoploid species. For example, the day-neutrality of the cultivars 'Seascape' and 'Tribute', and 'Tristar' are the result of introducing *F. virginiana* ssp. *glauca* into their pedigree (Bringhurst 1991). *Fragaria* × *ananassa* cultivars are described as either short-day cultivars, which form flower buds during photoperiods of short days (long nights), or day-neutral cultivars, which do not require short photoperiods to form buds. There is also a growing interest in developing cultivars with increased nutritional value, with a focus on secondary metabolites and anthocyanins (Just 2004, Crosby et al. 2007, Khanizadeh et al. 2007, Scalzo et al. 2007, Yoo et al. 2007), the success of which may be increased by gene introgression from wild species.

Development of new cultivars is not limited to intra- and inter-specific breeding within *Fragaria*. For example, 'Pink Panda' is the result of intergeneric hybridization of *F*. × *ananassa* with *Potentilla palustris* (Ellis 1962, Ellis 1991), now classified as *Comarum palustre* L. (Crow et al. 2000, Lundberg et al. 2009). *Potentilla palustris* differs from all the other *Potentilla* species in that it has "a large fruit with a large but non-succulent spongy receptacle" (Ellis 1962).

Marker-assisted breeding

The mission of the USDA-SCRI funded RosBREED project has been to develop highthroughput genotyping platforms to facilitate marker-assisted breeding in peach, apple, cherry and strawberry. The development and commercialization of the IStraw90 (International Strawberry 90K) SNP Array based on the Affymetrix Axiom ® platform is such a tool for strawberry (Bassil et al. manuscript submitted). The Array for genotyping strawberry contains 95,062 marker sites distributed in mostly genic sites across the genome.

Overview of Dissertation

The body of my Dissertation consists of three chapters. As detailed below, the first two chapters employ a new tool for genotyping in strawberry, called the IStraw90 Array, which I will refer to simply as the Array. The third chapter looks at verticillium resistance in strawberry and employs pedigree-based tools to identify sources of resistance.

<u>Chapter I</u> - A high density linkage map of the ancestral diploid strawberry, F. iinumae using SNP markers from the IStraw90 Array and GBS, includes a thorough review of all of the results from the Array genotyping of a subset of the F. iinumae mapping population that included the two founders, the F1 parent, and 21 F2 individuals. Also included in the first chapter, is the application of genotyping-by-sequencing (GBS) to a larger subset of the *F. iinumae* mapping population. *Fragaria iinumae*, an ancestral diploid of strawberry provided a model to: 1) understand and utilize the results from the Array; 2) evaluate the performance of the Array; 3) construct the first high density map for *F. iinumae*; and 4) to inform the analysis of octoploid data. The study of *F. iinumae* as reported in Chapter I validated the Array as a very useful tool and GBS as a complementary tool and informed the decision for a concerted focus on the use of the Array for genotyping of the octoploid breeding population. The bioinformatics methods employed for the diploid data in Chapter I guided the analysis of the octoploid data in Chapter II.

<u>Chapter II</u> - *Pedigree-based analysis of flower color variation using SNP markers from the IStraw90 Array* describes the development of a Closed Pedigree Set. The Closed Pedigree Set is based on three founders, two with white (W) flower color, and one with non-white (NW) flower color. The NW flowers varied in hue from light pinks and corals to orange and scarlet reds. The objectives were to develop hybrids with red flower color and to advance the potential for marker-assisted breeding by identifying marker-trait associations.

<u>Chapter III</u> – Germplasm resources for verticillium wilt resistance breeding and genetics in strawberry (Fragaria) describes the results of trials conducted in the greenhouse involving diploid and octoploid germplasm. A pedigree of the tested cultivars was developed and overlaid with results of detailed research of previous studies published on cultivar resistance to verticillium wilt. Resistance \times susceptible hybrids were developed for the purposes of conducting genetic studies in the future. Cultigens were identified as resistant and susceptible as an information resource relevant to breeding for resistance, which may inform choice of germplasm for additional screening and parent selection as well as future efforts to identify associations between markers and resistance traits. In association with my Dissertation project, I am a co-author on a recently submitted manuscript on the design and evaluation of the IStraw90 Array (Bassil et al. manuscript submitted). The Array contains a total of 138,099 probe sets including replicated probe sets. The Array can detect up to 95,062 unique SNP probe sets for each plant sample. The Array includes 3,751 SNP probe sets that were especially based on *F. iinumae*, 85,663 probe sets based on discovery in an octoploid germplasm panel, and 5,648 speculative "codon-based" probe sets. The data included in Chapter I and II are outcomes from the first use of the Array. I am also a co-author on a RosBREED publication about strawberry phenotyping protocols (Mathey et al. 2013) and co-author on *F. iinumae* mitochondrial (Mahoney et al. 2009) and chloroplast (Davis et al. 2009) publications.

CHAPTER I

A HIGH DENSITY LINKAGE MAP OF THE ANCESTRAL DIPLOID STRAWBERRY, F. IINUMAE, USING SNP MARKERS FROM THE ISTRAW90 ARRAY AND GBS

Abstract

An ancestral form of diploid Fragaria iinumae is recognized as a subgenome donor to the octoploid strawberry species, including the cultivated strawberry, Fragaria × ananassa. Here I report the construction of the first high density linkage maps of F. iinumae. These maps will serve as the basis for comparisons of genome structure among Fragaria species, for analyzing trait variation in F. iinumae, and for anchoring the assembly of an F. iinumae reference genome sequence. The segregation data sets used for construction of the linkage maps were generated by genotyping an F2 population derived from a cross between two divergent F. iinumae accessions that were collected from the wild in Japan. SNP (single nucleotide polymorphism) genotyping was based on two high-throughput platforms, the newly released Affymetrix IStraw90® Strawberry SNP Array, and Genotyping-by-Sequencing (GBS). The maps are based on Array and/or GBS segregation data from two subsets of an F2 mapping population (F2D): the 21F2D map is based on Array and GBS data from 21 F2D progeny; while the 85F2D map is based on GBS data from 85 F2D progeny, including the 21 from the 21F2D subset. The mapped markers are well-distributed across the expected 7 linkage groups. The 21F2D map has a length of 486.7 cM, and has 4,110 (3,215 Array and 895 GBS) markers at 158 loci. The 85F2D map has a length of 447.3 cM, with 895 GBS markers at 217 loci.

Introduction

The octoploid (2n = 8x = 56) cultivated strawberry, *Fragaria* × *ananassa*, and its immediate octoploid ancestors F. chiloensis and F. virginiana are recognized as having an allopolyploid genome composition (Rousseau-Gueutin et al. 2009, DiMeglio et al. 2014), which means that they have arisen from multiple diploid ancestors via processes of hybridization and chromosome number doubling (polyploidization). The most widely cited subgenome composition model for the octoploid genome is that of Bringhurst (1960). In this AAA'A'BBB'B' model (Bringhurst 1990), the letters A, A', B, and B' represent subgenomes, each of which is present in two copies within the overall octoploid genome. The A-type (A and A') subgenomes are considered to be highly differentiated from the B-type (B and B') subgenomes, while less differentiation exists between A and A', and between B and B'. Diploid Fragaria vesca is widely considered to be the source of an A-type genome (Senanayake et al. 1967, Potter et al. 2000, Folta et al. 2006). In the past decade, phylogenetic and other evidence has accumulated implicating an ancestral form of diploid (2n = 2x = 14), F. iinumae, as a second diploid progenitor and B-type subgenome contributor to the octoploid Fragaria species (Folta et al. 2006, Davis et al. 2009, Mahoney et al. 2009, Rousseau-Gueutin et al. 2009, Staudt 2009, Isobe et al. 2013, Njuguna et al. 2013, DiMeglio et al. 2014). At present, the F. vesca 'Hawaii4' (FvH4) reference assembly (Shulaev et al. 2011) is the only sequenced reference genome for strawberry. A goal of the Davis group is to assemble a reference genome for F. iinumae. The Davis research group is also engaged in developing germplasm resources for F. iinumae, including various F. iinumae hybrids. The assembly of plant reference genomes is reliant upon a process of "anchoring" assembled sequence scaffolds to a genetic linkage map. As a step toward assembling the *F. iinumae* genome, a mapping population was developed, and the first genetic linkage maps of *F. iinumae* was constructed, as reported here.

The construction of a linkage map relies upon marker segregation data from an appropriate progeny population, such as the F2 generation of a cross between genetically distinct parents. A linkage map establishes the linear order of marker loci along each chromosome, and defines the recombination frequencies between markers, where recombination frequency (RF) is expressed in units of centi-Morgans (cM), and 1% RF = 1 cM. Thus, the lower the recombination frequency between markers, the shorter the map distance between markers. For anchoring the assembly of the published *F. vesca* FvH4 reference genome (Shulaev et al. 2011), a linkage map was employed that was based on an F2 mapping population derived from a cross of *F. vesca* '815' × *F. bucharica* '601' (FV×FB) (Sargent et al. 2011). The respective FV×FB F2 mapping population consisted of 76 seedlings, and was genotyped with Single Sequence Repeat (SSR) markers (Sargent et al. 2011). The SSR marker segregation data were used to construct a genetic linkage map of seven linkage groups (LGs). The FV×FB map has a length of 444.8 cM, with 411 markers distributed over the seven linkage groups, corresponding to the seven chromosomes in the basic (x = 7) diploid strawberry genome.

Fragaria iinumae is distributed in the Russian Far East (Sakhalin) and in Japan (Staudt 2005, Hummer et al. 2006, Iketani et al. 2010). During a collection trip in 2004 to Hokkaido, Japan, among numerous accessions collected (Hummer et al. 2006, Davis et al. 2009), Tom Davis and Kim Hummer collected two *F. iinumae* accessions, J17 and J4, which are now maintained by the National Clonal Germplasm Repository (NCGR) in Corvallis, Oregon, under the accession numbers FRA1855 (PI637969) and FRA1849 (PI637963), respectively (Figure 1.1). These two accessions were crossed by Davis to generate an F1 hybrid (F1D), which was

then allowed to self-pollinate to generate an F2 generation mapping population referred to as the F2D population (Figure 1.2). This population is maintained at the UNH McFarlane greenhouses and the Woodman Farm (Figure 1.3). The F2D population was expected to segregate with respect to numerous molecular markers based on a previous genetic diversity study that included J4 and J17 (Njuguna et al. 2011). The F2D population provides a necessary resource for linkage analysis and construction of the first high density linkage map for *F. iinumae*.

Figure 1.1: Hokkaido, Japan – 2004 fruit germplasm expedition team and collection route. The collection route is traced with a yellow line on the map. Arrows indicate collection sites for the J17 and J4 accessions used for development of the mapping population.

The segregating genetic markers for linkage map construction were obtained by employing two molecular marker methodologies: array based SNP genotyping and GBS. While both the Array and GBS approaches generate information in the form of SNP genotype calls, the two approaches utilize very different mechanisms to generate these calls. The principles and practical aspects of these two approaches are briefly reviewed below.

Figure 1.2: *F. iinumae* **mapping population.** The F2 mapping population derived from F1D, an F1 hybrid derived from a cross of $J17 \times J4$. A subset of the population was genotyped for linkage map construction.

Figure 1.3: *F. iinumae* **mapping population maintenance.** As pictured from top to bottom, plants were grown at the UNH Horticultural Woodman Farm in matted rows mulched with saltmarsh hay, or in plasticulture, and at the UNH MacFarlane Greenhouses in 6" pots.

Array-based SNP genotyping

A SNP genotyping array is a kind of microarray (Gresham et al. 2006), in which tens or hundreds of thousands of short DNA molecules, which serve as probes or primers, are anchored to a surface within a small (5.5 mm in diameter) chamber (Figure 1.4). The chambers are arranged on a grid that mirrors the structure and dimensions of a 96 or 384 well microtiter plate, thus 96 or 384 genomic DNA samples can be processed at one time. Fragmented genomic DNA from each individual of interest is introduced into its own chamber, followed by instrumentally controlled annealing processes that result in the generation of fluorescent signals at the sites where genomic fragments have annealed to complementary probes. The colors and intensities of the fluorescent signals are then digitally recorded. The fidelity of the annealing process is so high that single nucleotide polymorphisms (i.e., SNPs) in otherwise identical DNA molecules can be differentiated, thereby allowing the genotype of the tested individual to be determined (or "called") at each of several thousand genetic loci.

The design of a genotyping array probes depends on prior discovery of SNP loci on the basis of sequence alignments and variant calling in comparison to a reference sequence. Conserved 24 to 33 bp of sequence on either the 5' or the 3' end of the SNP are needed for the design of primers, which are anchored onto the array, and are designed to complement the genomic sequences of interest (Figure 1.4). Generally two colors of 'hapten' labeled solution probes are utilized to pair to a specific base for detection of SNPs; one color for G or C and second color for A or T bases. As such, the detection process cannot differentiate A from T or C from G; therefore G/C and A/T SNPs are generally excluded in the array design process.

In a diploid species, true SNPs are di-allelic (i.e., no more than two alleles of a marker can exist in an individual), and their detection on the array results in clear genotyping cluster plots which display and differentiate the genotypic classes in the studied population (Figure 1.5). Tri-allelic and tetra-allelic levels of polymorphism can occur in polyploid species, where they add to the complexity of genotype calling (Bassil et al. manuscript submitted); however, the occurrence of polyploid-like cluster patterns in a diploid species (Figure 1.5) are indicative of a problem with the marker, such as paralogy (occurrence of the marker locus in more than one genomic site), or of incorrect reference sequence assembly.

As part of the USDA Specialty Crop Research Initiative RosBREED project (http://www.rosbreed.org), a strawberry 'IStraw90' Array was designed, built and evaluated on an Affymetrix® Axiom platform (Bassil et al. manuscript submitted). I made significant contributions to this project and am a co-author of the submitted paper (Bassil et al. manuscript submitted). The design of the IStraw90 Array was based primarily on prior SNP discovery in an octoploid germplasm panel. The SNP discovery process relied primarily on separate sequence alignments and variant calling for the octoploid panel members in comparison to the FvH4 reference sequence. However, SNP discovery was also performed on the *F. iinumae* hybrid F1D, and 3,751 of these "F1Dsnp" markers were incorporated into the Array. Thus, to the benefit of this project, the Array could be used to genotype the members of the *F. iinumae* F2D mapping population. A speculative, non-discovery-based "codon based" approach was also explored (Bassil et al. manuscript submitted).

Figure 1.4: Affymetrix Axiom® Array process and genotyping. A. The sample plate (left) holds fragmented genomic DNA samples from 96 individuals. Each sample is loaded into its own array chamber on the Array plate (right). **B**. Within each array chamber, genomic DNA fragments anneal to complementary probes that are anchored to the array. **C.** Allele-specific ligation event result in an allele-specific fluorescent signal.

Figure 1.5: Examples of cluster diagrams with different cluster quality classes. Within each diagram, each colored dot corresponds to an individual, and the dot location is indicative of a SNP genotype. Based upon the dot locations and cluster resolutions, the Affymetrix GTC and SNPolisher software programs "calls" the genotype of each individual, and assigns a dot color corresponding to that genotype. The *PHR* class is the highest quality class, because it discerns and clearly distinguishes among the three expected genotypic classes: homozygous AA (red dots), heterozygous AB (yellow dots), and homozygous BB (blue dots).

Unlike the SNP arrays recently published for other Roseaceae crops; apple (Chagne et al. 2012), peach (Verde et al. 2012), and cherry (Peace et al. 2012), which contain up to 9,000 SNPs on an Illumina ® Infinium ® genotyping platform, the strawberry Array comprises over 90K (90,000) SNPs on an Affymetrix Axiom platform (Bassil et al. manuscript submitted).

Genotyping-by-sequencing (GBS)

GBS is a non-discovery based approach for reduced representation of the genome. GBS relies on selected restriction endonuclease enzymes for fragmenting, followed by ligation of linker molecules to the cut ends of the genomic DNA fragments, and PCR amplification and size selection processes that result in a reproducible subset of genomic DNA fragments, thereby achieving reduced genomic representation. The reduced representation fragment pool is then subjected to high throughput sequencing. The GBS methodology has been successfully applied to wheat, barley, and switchgrass (Poland et al. 2012, Lu et al. 2013). One enzyme approaches using ApeKI have been successful (Elshire et al. 2011), and seem most appropriate for small genomes. A GBS approach with two methylation sensitive enzymes MspI and PstI has been utilized to enhance representation of genic regions and minimize the representation of repetitive regions, and to enhance the read depth as outlined by (Poland et al. 2012). An additional increment of complexity reduction is achieved with the two enzymes as compared with the one enzyme approach, which translates to increased read depth for the remaining represented segments of the genome. Thus, the two-enzyme approach is well suited to large genomes, including those of polyploid plants.

Array and GBS comparison

The design of a SNP array is based on prior SNP discovery, and provides genotype calls only for the SNP loci that have been programmed onto the array. In contrast GBS requires no prior discovery, and in fact results in the de novo discovery of the very SNP loci that are genotyped. Both platforms utilize sequence data, but in different ways. An array utilizes sequence data for SNP discovery and probe design, while producing data in the form of cluster plots (Figure 1.5) and genotyping calls. In contrast, GBS produces new sequence data for each of the genomic samples, and these sequences must then be aligned to each other and/or to a reference sequence to discover the SNP loci, if present, and to generate their respective genotyping calls. An array is limited to genotyping of SNPs discovered within the discovery germplasm panel, when compared to sequence provided in a reference genome. GBS requires no prior discovery and is not thus constrained.

Both the Array and GBS (when using methylation sensitive enzymes) were intended to survey genes and avoid repetitive regions. It was expected that the two platforms would sample similar portions of the *F. iinumae* genome, but that GBS would also sample regions not evident or present in the *F. vesca* FvH4 reference genome sequence and therefore not discoverable in the Array SNP discovery process. Thus, the genotyping platforms were selected to complement each other to provide comprehensive coverage of the gene-rich regions of the genome.

Materials and Methods

Plant material

The plant material consisted of *F. iinumae* accessions J17, J4, F1D (an F1 derived from a cross between J17 and J4), and subsets of an F2 mapping population (F2D) of 150 siblings derived from a self-pollination of F1D (Figure 1.2). The population and parents were maintained in pots at the UNH McFarlane greenhouses and in matted rows at the UNH Woodman Farm (Figure 1.3). Of the 150 F2Ds, 88 were genotyped by GBS, of which 21 were also genotyped on the Array.

DNA isolation

Young, furled leaf tissue was collected into 1.5 ml microfuge tubes on ice, and stored frozen at -80C. The tissue was lyophilized to minimize degradation during the isolation process. Just prior to freeze drying, leaf samples were taken out of the -80°C freezer, the caps were quickly opened and the tissue was pre-conditioned at -20°C for 1 to 2 hours. The samples were then freeze dried (Labconco, Kansas City, MO) under vacuum at 0.20 to 0.25 mbars with a condenser temperature of -60°C to -80°C for 48 hours and without the use of a heat plate. Immediately upon completion of freeze drying, the microfuge tubes were quickly closed and the lyophilized tissue was stored at -80°C until ready for the DNA isolation. For the Array, the lyophilized leaf tissue was shipped to Nahla Bassil and the DNA was isolated by her group. The DNA for both genotyping platforms was isolated using the E-Z® 96 Plant DNA kit (Omega biotek, Inc) following (Gilmore et al. 2011), with modifications. Here described in detail, is the procedure executed at UNH. In preparation for the DNA isolation, the lyophilized leaf tissue

was pulverized. A 10-15 mg weight of each lyophilized sample was placed into a individual cluster tubes (Corning 4413/4418) containing a 3 mm tungsten carbide bead, capped and the tube rack was floated on liquid nitrogen briefly (until the nitrogen bubbling calmed). The tube rack was then secured in the Mixer Mill MM100 (Retsch GmbH) for three sessions of 30 second pulverizing at frequency of 30 cycles/sec with intermediate cooling with liquid nitrogen. The pulverized leaf tissue was equilibrated to -20°C in preparation for isolation using the E-Z® 96 Plant DNA kit, including the use of Proteinase K as required by Affymetrix.

The DNA for the Array was quantified with Quant-ITTM PicoGreen® dsDNA at 485nm/535nm for 1.0 second using a Tecan infinite® 200 (Tecan Austria GmbH) microplate reader. The DNA for GBS was quantified with QubitTM fluoremeter (Invitrogen Corp) and as an indication of the DNA quality, the absorbance ratios of 260/280 and 260/230 were determined on a NanoDrop ND-1000 (NanoDrop Technologies, USA). Aliquots of 2 μ l of a random selection of the DNA samples were run on 1.0% standard agarose gel electrophoresis to access the integrity of the DNA (lack of degradation). For the Array, a minimum of 750 ng of DNA was provided, the DNA samples were diluted with TE (10 mM Tri-HCl, 0.1 mM Na2-EDTA) to a 15 η g/µl concentration. For GBS, a DNA quantity of 1 µg was provided in sample concentrations ranging from 28 to122 η g/µl.

SNP discovery

Genomic DNA from F1D was sequenced at the University of Illinois on one lane of Illumina HiSeq 2000 100 x 100 bp paired end reads (300 bp fragment size) from which 17,518 SNPs were discovered using an internally developed bioinformatics pipeline, and 3,751 of these SNPs were incorporated into the Array (Bassil et al. manuscript submitted).

Genotyping Array marker data

The Array data set was generated on the IStraw90 Array designed by the RosBREED *Fragaria* SNP consortium (Bassil et al. manuscript submitted). The Array includes 3,751 SNPs based on discovery in the F1D genomic sequence (F1Dsnps), 85,663 SNPs based on an octoploid strawberry discovery panel (octoploid-based SNPs), and 5,648 codon-based SNPs. The octoploid-based SNPs are further subdivided by discovery categories (Bassil et al. manuscript submitted), as described in Table 1.1. The two founding parents J17 and J4, the F1D parent, and 21 of the F2 population chosen at random were genotyped on the Array.

Table 1.1: Counts of IStraw90 Array SNPs by category. The primary categories are the *F*. *iinumae* diploid-based F1Dsnps, octoploid-based, and codon-based SNPs.

Marker name	Count	Description
F1Dsnp	3,751	Discovered in F1D
Octoploid-based		
Snp	63,263	SNP with two alternate alleles
mSnp	1,761	SNP with four alternate alleles
ins	4,615	An insertion
del	4,913	A deletion
SnpSnp	7,092	Subgenome-specific SNP adjacent to a marker SNP
indelSnp	1,176	Subgenome-specific indel adjacent to a SNP
SnpinIns	2,007	SNP inside a subgenome-specific insertion (insertion relative to <i>F. vesca</i> reference)
SnpinDel	836	SNP inside a subgenome-specific insertion (deletion relative to <i>F. vesca</i> reference)
Octoploid-based total	85,663	Discovered in octoploid germplasm panel
Codon-based	5,648	Non-discovery based SNP candidates
Array Total	95,062	All SNPs on the Array

Marker Type	Count
Octoploid-based total	85,663
F1Dsnp	3,751
Codon-based	5,648
Array Total	95,062

GBS marker data

A two enzyme GBS approach as outlined by (Poland et al. 2012) was executed by the Hubbard Center for Genome Studies (HCGS). A two enzyme system with the use of methylation sensitive enzymes *Msp*I and *Pst*I was chosen to enhance the read depth by reducing genomic representation, and to secure gene regions and minimize the representation of repetitive regions. A library preparation of the DNA from 95 genotypes and one negative control was sequenced on one lane of Illumina HiSeq 2500 100 x 100 bp paired end reads (300 bp fragment size) Single Flow Cell High Output Run Mode. The 95 genotypes included duplicates of J17, J4, and F1D, the 21 F2Ds plants genotyped on the SNP array, and an additional 68 F2D plants chosen at random.

Genotyping bioinformatics

The SNPs from the Array were genotyped using the Affymetrix Genotyping Console (GTC) and SNPolisher, with the standard default settings for diploid organisms. According to the Affymetrix rating system, the genotyped SNPs were classified into 6 cluster classes (Figure 1.5), of which the *Poly High Resolution (PHR)* class comprises the markers that meet the strictest quality criteria. The six cluster classes and their characteristics are as follows. 1) In the *PHR class*, cluster diagrams must contain highly distinct clusters, including both of the expected homozygous genotyping clusters. 2) The *Call Rate Below Threshold (CRBT)* class is exemplified by dispersed clustering and contains both of the expected homozygous genotyping clusters. 3) In the *Mono High Resolution (MHR)* class, there are less than two occurrences of the minor allele. 4) The *No Minor Homozygous (NMH)* class displays only two clusters and lacks one of the expected homozygous clusters. 5) The *Other (Oth)* class has distinct clusters but they are shifted off center and/or dispersed. 6) In the *Off-Target Variant (OTV)* class, the cluster plot displays indicative of aberrant annealing of probes. In addition, a seventh group of genotyping results for

mSNPs (designed to reduce complexity in the octoploid germplasm) were provided but these were not classified, and these are grouped as *Not Classified (NOCLS)*.

Markers suitable for linkage mapping using an F2 population were required to display three clusters in a cluster diagram. These three clusters represent the three expected genotypic classes: homozygous (AA), heterozygous (AB), and homozygous (BB), where A and B represent the alternate alleles of the marker locus. For convenience in the management and analysis of the marker data spreadsheet, the genotype clusters AA, AB, and BB are designated as 0, 1, or 2 respectively in the Array data output, while -1 indicates missing data. Thus, the 0 and 2 genotypes represent homozygosity for the alternate alleles, while the 1 genotype represents a heterozygous genotype.

The SNPs from the GBS dataset were identified using two pipelines, the Tassel 3.0 UNEAK (UN) non-reference based pipeline found at <u>http://www.maizegenetics.net</u>, and the referenced-based DW pipeline developed in the Davis lab by graduate student David Wood (unpublished). Implementation of the latter pipeline required a preliminary assembly of F1D sequence (D. Wood, unpublished) to serve as the reference genome.

Selection of Array and GBS markers for mapping

Markers of potential use for mapping were required to be heterozygous in F1D, and concordant in the parental trio (F1D and its parents J17, J4). Concordance exists when no trio member displays a genotype that could not exist given the genotypes of the other two trio members. Additional criteria for selection of GBS markers suitable for mapping were: 1) consistent genotype calls for replicates of J17, J4, and F1D, allowing no missing data; and a minimum sequence alignment read depth of six at each SNP. At a mean read depth of 6x (number of reads/SNP/individual), the error calling rate is expected to be minimized (Lu et al.

2013). One lane of Illumina HiSeq 2500/1500 sequencing generally provides about 200,000,000 reads, which based on the genome and reduced representation for 95 of *F*. iinumae individuals (J4, J17, F1D, all in duplicate; and 88 F2Ds) was estimated to result in a read depth exceeding 6x per allele, and expected to provide sufficient allelic representation to enable confident genotyping.

For linkage analysis using the JoinMap4.1 program (Kyazma B.V.) the marker genotypes were coded for an 'F2 population', according to the founding parent genotypes as described in Table 1.2. When the maternal parent was 0 or 2, it was replaced with an 'a'. When the paternal parent was 0 or 2, it was replaced with a 'b'. When either parent was a 1, it was replaced with an 'h'. Missing data as indicated by '-1' was replaced with '-'. Where the founding parents were both heterozygous, the replacements were made in both coupling and repulsion phases. In addition, the GBS data were sorted by quantity of missing data in the progeny, and initially any marker with two or more missing genotypes in the progeny was excluded.

Parents	s (Array	codes)	Code r	eplaceme	ents for J	Parents (JoinMap codes)				
J17	J4	F1D	0	2	1	-1	J17	J4	F1D	
0	2	1	a	b	h	-	a	b	h	
1	2	1	a	b	h	-	h	b	h

Table 1.2: Recoding of Array data for JoinMap. The replacement codes for F2D progeny genotypes are based on J17 and J4 parental genotypes, which occurred in the eight permutations indicated in the "Parents" column.

The Array markers with identical segregation patterns were grouped into genotypic bins and given a unique hundred-series bin name. Then, the GBS markers were added to the Array marker bins or into GBS-specific bins, as they were grouped by segregation pattern during the mapping process.

Linkage map construction

Two linkage maps were constructed using JoinMap 4.1(Van Ooijen 2006) with the Maximum Likelihood algorithm and the Kosambi mapping function. A minimum LOD (logarithm odds score) of 3.0 to group was specified and default settings were in effect for the remaining parameters. The correct phase of markers with heterozygous parental genotypes was determined during the mapping process as correct if mapped and incorrect if unmapped.

Markers that caused excess fit-stress of greater than ± 1 cM were excluded. The construction of the linkage maps was completed iteratively. A linkage map was initially constructed with only Array data for the 21 F2Ds. The GBS data were later incorporated. Plants with excessive missing data were excluded for the map construction. The resulting linkage map, the 21F2D map, including both the Array and GBS datasets for the 21 F2Ds, provided a framework for developing a GBS map for the 85 F2Ds: the 85F2D map.

Following construction of the two *F. iinumae* maps, the correspondences between the *F. iinumae* linkages groups (LGs) and the *F. vesca* pseudomolecules (PCs) were examined, to define the chromosomal patterns of homology between *F. iinumae* and *F. vesca*. This was done by using DNA sequence information to determine the locations of the mapped Array and GBS marker sites (in *F. iinumae*) within the *F. vesca* PCs. Sets of markers located on the same chromosome in two species are said to be syntenic (chromosomes from two different species

having common markers considered to be homologous). The linkage groups (LGs) of the F2D maps were then renumbered to correspond to the PCs of FvH4 with which they had the most synteny; F2D LGs were renamed LG1 through LG7 to correspond to PC1 through PC7 of FvH4.

Results

Array genotyping

The results of genotyping of J4, J17, F1D and 21 F2D individuals are summarized in Tables 1 through 4. In summary, of the 95,062 SNP markers on the Array, the number of SNPs that fell into each of the six cluster classes were as follows: 3,380 *PHR*, 2,605 *CRBT*, 71,682 *MHR*; 900 *NMH*; 12,827 *Oth*, 1,907 *OTV*, and 1,761 *NOCLS* markers (Table 1.3). Of the critically important *PHR* class, which was expected to provide the majority of the markers amenable to mapping, 3,171 were F1Dsnps (i.e., discovered in *F. iinumae* F1D), while 199 were octoploid-based (i.e., discovered in the octoploid germplasm discovery panel) SNPs, and 10 were codon-based SNPs (Table 1.3).

Selection of Array markers suitable for mapping

Although the Array provided genotype data for 95,062 SNP sites, only a minority of these SNPs sites was expected to be suitable candidates for map construction, and even fewer were expected to be successfully incorporated into the final linkage map. To be considered suitable for use in map construction, marker heterozygosity in F1D was required, because markers that were genotyped as homozygous in F1D would not be expected to segregate in the F2D population. Implementation of this criterion narrowed the marker candidate list to 13,245 (Table 1.4), in part by eliminating the entire *MHR* cluster class of 71,682 Array SNPs (Table 1.3), as would be expected because by definition the *MHR* markers are not heterozygous in any

population member, including F1D. Some markers from other categories were also eliminated by the F1D heterozygosity requirement.

Additionally, genotypic concordance with no missing data was required among the parental trio members (J17, J4, F1D): on this basis, 1,103 markers were eliminated (Table 1.5). Among the remaining 12,142 marker candidates, all of which exhibited heterozygosity in F1D and trio concordance, J17 and J4 did not share the same homozygous genotype with respect to 3,068 F1Dsnps, 554 octoploid-based, and 55 codon-based SNPs, while both J17 and J4 were called as heterozygous for 238 F1Dsnps, 7,264 octoploid and 963 codon SNPs (Table 1.5). The final list of F1Dsnps deemed suitable for map construction totaled 3,306, of which 3,022 were *PHR* class markers (Table 1.6a). In contrast, the final list of octoploid-based SNPs selected for map construction totaled 7,818, out of which only 168 were *PHR* markers (Table 1.6b). Finally, 1,011 codon-based SNP candidates were deemed suitable for mapping, of which only 7 were classified as *PHR* (Table 1.6c).

Table 1.3: Summary of Array genotyping results for all SNPs. The columns are subdivided for the SNPs types for the F1Dsnps, and the octoploid-based and codon-based SNPs.

GBS results

A potential count of 5,281 SNPs resulted from the UN pipeline. The DW approach resulted in 2,213 candidate SNPs. After filtering the datasets for missing data, non-concordance, and homozygosity for F1D, the UN pipeline provided 579 SNPs, while the DW pipeline resulted in 690 SNPs suitable for mapping. Three of the 88 F2Ds were excluded from the mapping dataset, due to a large amount of missing data; therefore the 85F2D map was based on 85 of the 88 F2Ds.

Map construction

When the SNPs deemed suitable for mapping were entered into the map construction process using JoinMap (Van Ooijen 2006), variable percentages of the markers of different categories and classes were successfully incorporated into linkage maps, as summarized in Table 1.6. The criteria for successful marker incorporation were: 1) incorporation into one of the seven expected linkage groups, with a LOD score of 3 or better; and 2) linkage group incorporation without artifactually lengthening of the map. With regard to the latter, artifactual lengthening can occur when the placement of a marker at its most highly probable position within the map implies the presence of highly localized double recombinants (sometimes called "singletons"), which are generally regarded as indicators of genotype misclassification (van Os et al. 2006). In such cases, the marker can be tentatively discarded from the data set, or the offending genotype calls can be changed to "missing data".

<u>Array markers</u> - Of the 3,306 F1Dsnps deemed suitable for mapping, 3,031 were successfully mapped, of which 3,008 were *PHR* F1Dsnps (Table 1.6b). Of the 298 F1Dsnps that could not be placed in the 21F2D map, 14 were *PHR* class markers that caused the map to

artifactually lengthen, while the remaining 284 unmapped markers were not *PHR* class markers, and either caused the map to lengthen or did not show any linkage. Of the 7,818 octoploid-based SNPs rated as suitable for mapping, only 177 including 166 *PHR* class markers could be placed on the 21F2D map. The final list of codon based SNPS suitable for mapping totaled 1,011, of which only 7 (all *PHR*) could be mapped (Table 1.6c).

The 21F2D map contains 3,215 Array SNPs (Table 1.7), of which 3,181 were *PHR* class including 3,008 F1Dsnps, 166 octoploid SNPs, and 7 codon-based SNPs. The 34 mapped, non-*PHR* SNPs included 14 *CRBT* F1Dsnps, 16 *Oth* (9 F1Dsnps, and 7 octoploid-based SNPs), and the remaining four *NOCLS* (mSNPs). The numbers of SNP markers mapped relative to the total number of markers of each category on the Array were tabulated (Table 1.7). The category with the highest proportion of mapped markers was the diploid F1Dsnps with 80.8%, while of the octoploid classes, the percentage mapped markers were low and ranged from 0.12% to 0.23% (Table 1.7). Overall, including all Array markers, the mapped SNPs were 98.9% *PHR* quality (Table 1.7), as expected for the highest quality genotyping cluster classification as illustrated in Figure 1.5.

<u>GBS markers</u> - The GBS sequence dataset analyzed by the two bioinformatics pipelines, a Tassel non-reference based UNEAK (UN) pipeline and a F1D *F. iinumae* reference-guided, internally developed pipeline (DW), resulted in 895 mapped markers distributed across the linkage groups in both linkage maps (Table 1.9). The mapped markers include 300 unique markers for the UN and 399 for the DW pipelines, and a total of 195 markers in common between the UN and DW pipelines. Of the 895 GBS markers, 21 were found to be identical to Array markers (Table 1.9). The 895 GBS markers that could be mapped in 21F2D were used to make the 85F2D map.

Table 1.7: Comparison of genotyped and mapped SNPs by cluster class and discovery group. The mapped percentage by class is the total number mapped divided by the total number genotyped for each class.

Linkage maps

The additional 895 GBS markers were added to the mapped Array markers for a total of 4,110 markers on the 21F2D map (Figure 1.6, Table 1.9 and Table A). In addition, the 895 GBS markers were used to construct the 85F2D map, which is based upon 85 F2D individuals and does not include any Array markers. The 21F2D and the 85F2D maps (Figure 1.6) contain 158 (Table 1.9 and Table B) and 217 (Table 1.9 and Table C) genotypic bins with map lengths of 486.7 and 447.3 cM, respectively. The number of markers per genotype bin was consistent across the linkage groups with an average of 26 for the 21F2D map and 4 for the 85F2D map (Table 1.9). A measure of map resolution is indicated by the recombination frequency; the lower the recombination frequency the higher the map resolution between any two loci. The minimum LOD on the 21F1D map was 1 for LG5. The additional genotypes in the 85F2D map resulted in greater resolution with the detection of additional recombination and increased the minimum LOD to 10 for each LG.

Representation of Array and GBS markers in the LGs – The mapped Array and GBS markers are uniformly distributed across the 7 LGs (Table 1.8). On the 21F1D linkage map (Figure 1.6), F1Dsnp-based SNPS are represented in 148 of the 158 loci. Of the remaining 10 loci, one locus includes only an octoploid-based marker and nine loci include only GBS markers. All of the loci in LG1 and LG7 are represented by F1Dsnp markers. All 19 loci of LG1 are represented by both F1Dsnp and GBS markers. LG2 has five loci represented by F1Dsnp markers, one locus represented by only GBS markers, and the remaining 15 loci are represented by both F1Dsnp markers and GBS markers. LG3 has seven loci represented by only F1Dsnps, four loci are represented by only GBS markers, while the remaining 19 loci are represented by both F1Dsnps and GBS markers. LG4 has two loci with only F1Dsnps, four loci with only GBS

markers, the remaining 11 loci are represented with both F1Dsnps and GBS markers. LG5 has five loci with only F1Dsnp markers, the remaining 18 loci are represented by both F1Dsnp and GBS markers. LG6 has six loci represented by only F1Dsnp markers, with 20 loci are represented by both F1Dsnp and GBS markers and one locus represented by an one octoploid-based del SNP, and this is the sole locus represented by only an octoploid-based SNP in all of the seven linkage groups. LG7 has 4 loci represented by F1Dsnps, and the remaining 17 loci are represented by both F1Dsnps and GBS markers.

<u>Heterozygosity and segregation distortion</u> - The founding parents, J4 and J17, were evaluated for heterozygosity in terms of the numbers and percentages of heterozygous markers. Among the SNPs deemed suitable for mapping, the 28.5% heterozygosity of J4 was more than three times that of 8.8% for J17, while among the SNPs that were actually incorporated into the maps, the relative level of heterozygosity of J4 is 25.6%, eight times higher than the 3.8% of J17 (Table 1.10). Overall there was little to no segregation distortion in the F2D map (Table 1.11, Figure 1.7 and Figure 1.8).

Figure 1.6: *F. iinumae* high density linkage map. The figure provides a comparison of mapping results for the 21F2D and the 85F2D linkage groups. For each linkage group, the 21F2D version is on the left and the 85F2D version is on the right. The linear orders of mapped loci within linkage groups are in agreement between the 21F2D and 85 F2D maps.

40

Table 1.8: Distribution of mapped markers by SNP type and F1D linkage group. 8a. The Array and GBS SNP marker distribution on the seven linkage groups and in total is provided. The last column provides the percentage conversion of the number of mapped SNPs to the total number of SNPs on the Array. **8b**. The table shows the distribution of markers from the two GBS bioinformatic pipelines, and itemizes unique and shared markers between the two pipelines and provides a tally of the number of mapped markers common between the Array and GBS. The two GBS pipelines were the UNEAK (UN) generated using non-reference based Tassel pipeline, and DWF1DRf (DW) generated by Dave Wood's developed *F. iinumae* reference based pipeline.

Table 1.10: Heterozygosity of J17 compared to J4 in suitable mapped and unmapped markers. The markers included were heterozygous in F1D and concordant in the trio. The total SNPs of each genotypic permutation is the sum of the SNPS from the three Array discovery groups. The total SNPs in each genotype group is the sum of the SNPs from the three Array discovery groups by genotypic groups of J17 and J4; homozygous for the alternate allele, J4 heterozygous, J17 heterozygous, and J17 and J4 both heterozygous. The last two columns indicate the relative heterozygosity of J17 and J4 in calculated at % number of markers heterozygous in J17 and J4 respectively, divided by the total number of markers in both 10a and 10b.

Figure 1.7: Genotypic frequencies across the seven LGs for 85F2D map. The expected frequencies of the three genotypes are shown with dotted lines. The Y axis represents the number of individuals from 0 to 85; the x axis represents the individual loci in each linkage group.

Figure 1.8: Allelic frequencies across the seven LGs for 85F2D map. The expected frequencies of A and B are 50% and are shown with a dotted line at 50%.

Comparison of F. iinumae F1D LGs to F. vesca FvH4 pseudochromosomes

A comparison of the F1D linkage groups to the *F. vesca* Hawaii4 v1.1 reference pseudochromosome (PC) physical map revealed high macrosynteny (Figure 1.9), but the degree of synteny varies for each LG (Figures 1.10 through 1.16 and Table 1.12), and within each of the LGs the degree of collinearity with FvH4 varies widely (Figure 1.17 to 1.23).

Overall an indication of synteny of F1D with FvH4 was calculated by dividing the number of markers syntenous with the homologous FvH4 relative to the total number of markers mapped for an overall value of 88.9%, ranging from a low of 85.9% for LG5 to a high of 95.2% for LG7 (Table 1.12). Correspondingly, 460 (11.2%) of the markers were identified with nonhomologous LGs, with a high of 108 markers to PC4, followed by 63, 62, and 57 markers to PC6, PC1, and PC3 respectively. The lowest frequency of markers identifying with other PCs includes 35, 30, and 25 markers to PC7, PC5, and PC1, respectively (Table 1.12). In addition, 13 markers had homology to PC0, which consists of scaffolds that could not be mapped using the FV×FB linkage map. The remaining 67 markers in the Misc category include 33 GBS markers from LG4 that have homology with two scaffolds in F. vesca v.1.1 scaffold database. The general syntenic relationships and significant departures from synteny are illustrated in Figures 1.10 through 1.16. LG1 (Figure 1.10) and LG2 (Figure 1.11) had the highest number of markers identifying to non-homologous PC6 with 30 and 17 markers respectively, of which of 30 and 4 markers, respectively were to the lower end of PC6. For LG3, the highest number of markers identified to non-homologous PCs were 23 marker to PC2 (Figure 1.12). LG4 could not be assembled as one linkage group until the GBS data were incorporated with the Array data (Figure 1.13), the non-discovery based GBS approach discovered SNPs that were not part of the F. vesca FvH4 reference genome but were found later found to be homologous to unmapped

scaffolds of FvH4. For both LG5 (Figure 1.14) and LG6 (Figure 1.15), the highest number of markers to non-homologous groups were to PC4 with 41 and 51 markers respectively. LG6 (Figure 1.15) also had many (48) markers with homology to PC1 from 19.1 to 19.9 Mbps. LG7 (Figure 1.16) had the highest conservation of synteny with *F. vesca* of any of the linkage groups at 95.3% (Table 1.12), with the highest non-conservation to PC3 with only 13markers.

The LGs are individually compared to their homologous PCs for collinearity (Figures 1.17 to 1.23). The figure legends include observations about potential inversions and other rearrangements. Although there is a degree of collinearity, there is not one LG without some level of rearrangement with respect to its homologous PC. Analogous to the synteny comparison, LG4 appear to have the least collinearity to PC4, and LG7 appears to have the most collinearity with PC7.

Figure 1.9: F1D synteny with FvH4. The top left figure provides an overview of synteny between the seven LGs of F1D and the PCs of FvH4. The remaining figures provide an overview of synteny and collinearity of each LG to FvH4.

Table 1.12: Synteny of *F. iinumae* **F1D to** *F. vesca* **FvH4.** The synteny is based on the percentage of markers on an LG that are syntenic with the corresponding F. vesca pseudochromosomes (PCs). For each LG, the LG with highest number of markers to a non-homologous PC are in bold.

* Markers with homology with FvH4 PC0, which includes scaffolds not mapped using the FV \times FB linkage map.

** For LG4, Misc includes 23 markers with homology to FvH4 v1.0 scaffolds: 8 markers to scf0513160a, and 15 markers to scf0513158b, and 10 with discernable homology with FvH4.

Figure 1.10: LG1 synteny with FvH4. Most (419 of 471, 89.0%) of the markers on LG1 are located on FvH4 PC1. Some LG1 markers are located elsewhere on the FvH4 genome. LG1 includes markers to non-homologous PCs including: 6 markers within the locus at 32.0 cM to PC5 from 21.8 to 21.9 Mbps; and 30 markers on the bottom 49.3 cM locus of LG1 to the lower end of PC6 from 35.3 to 37.7 Mbps.

Figure 1.11: LG2 synteny with FvH4. Most (544 of 590, 92.2%) of the markers on LG2 are located on FvH4 PC2. Some LG2 markers are located elsewhere on the FvH4 genome. For instance, at the 2.5 cM locus, 10 markers correspond to PC3 from 20.9 to 21.6 Mbps and 4 markers correspond to PC6 from 38.7 to 39.1 Mbps; and at the 17.3 cM locus, 11 markers correspond to PC6 from 13.3 to 13.8 Mbps.

Figure 1.12: LG3 synteny with FvH4. Most (567 of 647, 87.6%) of the markers on LG3 are located on FvH4 PC3. Some LG3 markers are located elsewhere on the FvH4 genome including at locus 78.9 cM: 19 markers homologous to PC2 from 23 to 24.1 Mbps; 6 markers homologous to PC4 from 6.6 to 6.9 Mbps; 13 markers homologous to PC7 from 0.18 to 0.6 Mbps; and 5 markers homologous to PC7 from 13.1 to 13.4 Mbps.

Figure 1.13: LG4 synteny with FvH4. Most (431 of 484, 89.0%) of the markers on LG4 are located on FvH4 PC3. Some LG4 markers are located elsewhere on the FvH4 genome; at the 0.0 cM locus, 6 markers have homology to PC5 from 25.2 to 26.2 Mbps and 3 markers have homology to PC6 from 10.3 to 11.7 Mbps. Nineteen of the markers on LG6 defining the loci from 4.8 to 40.8 cM do not have homology to any FvH4 PCs. However when these same 19 markers were compared to Hawaii4 v1.1 scaffolds, the seven markers at 4.8 cM shared high identity to scf0513160a, and the remaining twelve markers from 15.03 to 40.48 cM had high identity to the scaffold 0513158b and to FvH4 v1.0 PC4.

Figure 1.14: LG5 synteny with FvH4. Most (487 of 562, 86.7%) of the markers on LG5 are located on FvH4 PC4. Some LG5 markers are located elsewhere on FvH4 genome including: 39 markers within four loci from 46.0 to 53.4 cM have homology to PC4 from 13.2 M to 14.0 Mbps; and at the 68.2 cM locus, 7 markers with PC1 from 3.3 to 5.1 Mbps, 7 markers with PC3 from 11.6 to 11.9 Mbps, and 4 markers with PC7 from 8.1 to 8.2 Mbps.

Figure 1.15: LG6 synteny with FvH4. Most (792 of 922, 85.9%) of the markers on LG6 are located on FvH4 PC6. Some LG6 markers are located elsewhere on the FvH4 genome including 31 markers within 3 sequential loci from 24.0 to 31.58 cM have homology with PC1 from 19.1 to 19.9 Mbps; and at one locus at 44.7 cM, 14 markers have homology with PC3 from 3.4 to 3.7 Mbps, 4 markers are homologous with PC3 from 18.7 to 21.7 Mbps, 7 markers to PC4 from 0.04 to 0.2 Mbps, and 19 markers have homology to PC4 from 21.9 to 23.9 Mbps. Additionally at 62.2 cM, 24 markers are located on PC4 from 10.0 to 10.3 Mbps.

Figure 1.16: LG7 synteny with FvH4. Most (413 of 434, 95.2%) of the markers on LG7 are syntenic with PC7. Some LG7 markers are located elsewhere on FvH4 genome including 13 markers at locus 0.0 cM with homology with PC3 from 10.0 to 10.7 Mbps.

Figure 1.17: LG1 collinearity with PC1. The top end of LG1 from 0.0 to 27.1 cM shows signs of three separate inversions: 1) three loci and 33 markers to PC1 from 0.86 - 0.72 Mbps; 2) eight loci and 84 markers to PC1 from 1.5 - 3.1 Mbps; and 3) three loci and 46 markers to PC1 from 4.7-5.5 Mbps. LG1 with seven loci from 32.0 to 49.3cM (293 markers), appears collinear with PC1 from 5.4 to 20.9 Mbps. The locus at 49.3 cM with 111 markers has homology with PC1from 8.8 to 20.9 Mbps.

Figure 1.18: LG2 collinearity with PC2. LG2 is rearranged with respect to PC2. LG2 loci at 2.5 and 5.0 cM with 72 markers have an inverted homology to PC2 from 5.3 to 9.3 Mbps. At the current map resolution, it is unclear whether or not the markers at 5.0 cM are inverted with respect to PC2 from 0.2 to 2.3 Mbps. The locus at 7.42 cM includes 6 markers with homology to PC2 from 3.1 to 3.4 Mbps. The LG2 locus at 17.3 cM has homology to PC2 from 2.3-2.4 Mbps and also has homology to 17.4 to 18.5 Mbps while the preceding and following loci at 12.3 and 19.74 cM have homology to PC2 from 16.9 to 17.3 and 18.1 to 18.4 Mbps respectively. The loci from 19.7 to 22.2 cM (37 markers), 22.2 to 42.2 cM (117 markers), and from 44.7 to 59.5 cM(73 markers) have homology to FvH4 PC2 from 17.5 to 18.4 Mbps, 18.6 to 21.3 and 21.5 to 22.7 Mbps as three separate inverted regions.

Figure 1.19: LG3 collinearity with PC3. LG3 has 14 loci from 0.0 to 53.6 cM (101 markers) with an inverted homology with respect to PC3 from 0.05 to 1.5 Mbps. Additionally, the four loci from 53.61 to 61.3 cM (38 markers) and the two loci from 61.3 to 63.8 cM (14 markers) have an inverted homology to PC3 from 1.5 to 3.3 and 3.7 to 4.0 Mbps, respectively. The 7 loci from 66.5 to 84.0 cM (378 markers) are collinear with PC3 from 4.3 to 23 Mbps. A rearrangement is indicated from 84.0 to 91.4 cM (81 markers) and from 91.4 to 99.0 cM (13 markers) with homology to PC3 from 28.7 to 31.0 and from 27.9 to 28.5 Mbps, respectively. Finally indel rearrangements are indicated at within two loci: at 78.9 cM (6 markers) and at 99.0 cM (10 markers) with homology to 31.5 to 31.8 and 30.6 to 30.7 Mbps, respectively.

Figure 1.20: LG4 collinearity with PC4. LG4 at the locus at 0.0 cM (131 markers) is collinear with PC4 from 0.5 to 16.4 Mbps, while two of the markers at 0.0 cM locus and 88 markers at 2.4 cM locus have inverse homology to PC4 from 9.2 to 22.8 Mbps.

Figure 1.21: LG5 collinearity with PC5. On LG5, the 19 loci (273 markers) from 0.0 to 58.3 cM are collinear with the PC5 from 0.14 to 8.4 Mbps. However from 58.3 to 68.2 cM (5 loci, 54 markers), there is evidence of multiple inversion and rearrangements with respect to PC5.

Figure 1.22: LG6 collinearity with PC6. On LG6, a number of loci appear inversely collinear with PC6: 56 markers at loci 0.0 to 9.83 cM to PC6 from 0.2 to 1.6 Mbps, 95 markers within loci 42.2 and 44.7 cM to PC6 from 4.2 to 8.3 Mbps, and 66 markers at loci 82.3 to 98.2 cM to PC6 from 37.6 to 38.7 Mbps. An indel is indicated at locus 62.2 cM with 17 markers with homology to PC6 from 1.5 to 2.0 Mbps inserted between the locus at 60.0 cM and part of the locus at 62.2 cM which have homology to PC6 from 33.6 to 33.8 Mbps and 33.9 and 34.0 Mbps, respectively.

Figure 1.23: LG7 collinearity with PC7. On LG7, an inversion with PC7 is observed in three separate regions of sequential loci: 1) loci at 0.0 and 2.4 cM (125 markers) from 0.9 to 13.2 Mbps; 2) loci at 2.4 and 4.9 cM (36 markers) from 13.4 to 15.3 Mbps, and 3) the 11 loci from 24.4 to 51.5 cM (119 markers) from 19.3 to 22.5 Mbps.

Discussion

The construction of the first linkage maps in the ancestral diploid strawberry species, Fragaria iinumae, is reported here. The two constructed maps (Figure 1.6 and Table 1.9) converge on a mutually consistent description of linkage group structure and linkage map length in F. iinumae, but differ in two important ways: map resolution and numbers of markers. The 21F2D map (Table 1.9) incorporates the most markers (4,110), but these markers are separable into only 158 loci, resulting in an average map resolution of 2.70 cM/locus, as compared with the theoretical maximum of 2.38 cM/locus. The 21F2Dmap LOD averaged of 3, with a couple of troublesome linkages on LG3 and LG5 which had respective LOD scores of 2 and 1 respectively. The order of the problematic linkages in the map of 21F2D was affirmed in the map of 85F2D; the additional data permitted detection of additional recombination between markers. In contrast, the 85F2D map has a minimum LOD of 10 and has substantially fewer markers (895), but they were separable into 217 loci, resulting in an increased map resolution of 2.06 cM/locus as compared with a theoretical maximum of 0.58 cM/locus. Thus, the 85F2D map achieved better resolution, but the 21F2D map resolution of 2.70 cM/locus came closer to achieving its theoretical maximum resolution of 2.38 cM/locus. The comparative shortfall of the 85F2D map in achieving its maximum theoretical resolution is likely due to the low quality of the GBS data, as discussed later. It is anticipated that future incorporation of Array SNP data along with GBS data for all 85 plants used to construct the 85F2D map will result in a next generation map that achieves both high resolution and high marker number. That next generation map will serve to anchor the F. *iinumae* genome assembly that is now in progress.

The total map lengths of 486.7 and 447.3 cM, respectively, for the *F. iinumae* 21F2D and 85F2D maps are similar to the range of 406.3 to 445 cM reported for other diploid strawberry maps (Davis et al. 1997, Sargent et al. 2011, Tennessen et al. 2013). The linkage map used to anchor the FvH4 physical map is based on the FV×FB linkage map with 411 SSR loci for a total map length of 444.8 cM (Sargent et al. 2011). The FV×FB map is comparable in length to the *F. iinumae* map, although it has over twice the number of loci compared to the F1D maps.

Heterozygosity and segregation distortion

Analysis of both the linkage map for segregation distortion and for allelic representation shows close to a Mendelian segregation ratio of 1:2:1 as expected and close to the expected normal 50:50 ratio of A and B alleles (Table 11a and b, Figure 1.7 and 8, respectively). These normal segregation ratios contrast to the segregation distortion observed in the *F. vesca* \times *F. vesca* and *F. vesca* \times *F. bucharica* FV×FB maps (Davis et al. 1997, Sargent et al. 2006). The difference in segregation distortion between the maps may be due to a differences in nuclearorganelle genome compatibilities (Davis et al. 2009), which were more likely to be a factor in the wide intraspecific *F. vesca* \times *F. vesca* (Davis and Yu, 1997) and interspecific *F. vesca* \times *F. bucharica* (Sargent et al., 2006) crosses used to generate the respective mapping populations. In contrast, the *F. iinumae* J17 \times J4 cross involved closely related, conspecific parents that would have been unlikely to have accumulated significant nuclear or organelle genomic divergences.

Marker performance

Construction of the two linkage maps provided numerous insights into the relative merits of various classes and categories of Array markers. In evaluating the performances of these marker classes and categories, it is important to recall that, of the 95,062 SNP markers (Table 1.1) interrogated by the IStraw90 array, only 3,751 were F1Dsnps, which were designed specifically to detect SNPs believed to be heterozygous in F1D and therefore expected to segregate in the F2D mapping population. In contrast, the 85,663 octoploid-based SNPs were known only to be polymorphic among the members of an octoploid germplasm panel, and the 5,648 speculative codon-based SNPs were not known to polymorphic in any particular population, so there was no *a priori* expectation that the octoploid- and codon-based Array SNPs would be informative in the F2D population. Thus, it was not at all surprising that 80.8% of the F1Dsnps were ultimately incorporated into linkage maps, while only 0.21% and 0.12% of the octoploid- and codon-based SNPs were so incorporated (Table 1.8). The high mapped conversion rate of 80.8% for F1Dsnps compared to the very low conversion rate of less than 1% for the octoploid SNP's (Table 1.8) indicates a strong correlation between the relatedness of the two types of discovery panels to that of the germplasm genotyped specifically; the lack of relatedness of F. iinumae to the F. vesca reference guided octoploid-based SNPs compared to the high relatedness of F. *iinumae* to the genotyped F. *iinumae* accessions.

Overall, 3.4% of the array markers were mapped (Table 1.7). Considering the performance of Array SNPs by cluster class, 94.1% of the *PHR* class was mapped, and very few with less than 1% of the other cluster classes were mapped (Table 1.7). The high conversion rate of the *PHR* class confirms the expected superiority of this class for utilization in mapping. Nevertheless, that fact that at least a few markers in other cluster classes achieved map

incorporation suggests that mapping should not be based exclusively on the members of the *PHR* class.

Array and GBS

The weakness and strengths of the Array and GBS process complemented each other in the assemblage of the *F. iinumae* map. Commonality of markers from the two approaches was very low, with only 21 markers in common (Table 1.8b), but common binning was very high, with GBS providing only 10 unique bins – i.e., bins that were not also defined by Array markers. A total of 30 bins did not have GBS markers. However, the GBS-specific bins were important because they added loci to the map, particularly in a region of LG4 that was not otherwise marked. The fact also points to a weakness of discovery-based technologies and a strength of the GBS technology. Genotyping of regions of the genome with a SNP array is limited to that contained in the reference genome. The weakness of the GBS approach is the large amount of missing data. LG4 was the most challenging linkage group to construct, and could only be assembled as one linkage group when the Array and GBS data were merged into one dataset.

21F2D map comparison to FvH4

A high degree of synteny (*or more properly conservation of synteny*) was observed between the marker distributions on the *F. iinumae* linkage groups (LGs) as compared with the *F. vesca* FvH4 pseudochromosomes (PCs). However, in more detailed comparisons between each LG and its corresponding PC, collinearity was not always evident, and evidence of paracentric inversional differences between *F. iinumae* and FvH4 was present near the ends of several LGs. The comparison of LGs and PCs indicates a putative translocation between chromosome 1 and 6, such that *F. vesca* and *F. iinumae* have different arrangements of these two chromosomes. There also seems to be a translocation between PC6 and LG1 and PC1 and LG6 (Table 1.12) with 30 and 48 markers respectively and LG6 has the most number of markers (130) to non-homologous PCs, with the most homology with PC4 and PC1. Alternately, these putative rearrangements could actually be artifacts of mis-assembly of the FvH4 genome. In support of the latter hypothesis, there are a considerable number of markers in loci that have homology to non-homologous PCs as evidence by Table 1.12 and Figure 1.10 to 16. Interestingly, of the PCs, PC4 has the most markers on non-homologous LGs, and LG4 was the most challenging LG to assemble (Table 1.12). The difficulty with assemblage of LG4 and the homology of PC4 with non-homologous LGs suggests that FvH4 PC4 may be incorrectly assembled.

Overall, the observed differences between the *F. iinumae* LGs and the FvH4 PCs suggest two important questions. First, to what extent are the differences real, and to what extent if any do they indicate errors in the FvH4 genome assembly? Notably, LG4 of the HK map, an *F.* ×*ananassa* map, generated as part of the RosBREED project, also presented problems for linkage group construction using Array data (Bassil et al. manuscript submitted). Also, difficulty in assembling LG4 in another octoploid map has been encountered (Dan Sargent, personal communications). The re-occurring difficulty with LG4 suggests that at least PC4 is likely to be incorrectly assembled in the *F. vesca* FvH4 genome.

Of the 8,465 SNPs heterozygous in F1D and also heterozygous in the parents, only 20 segregated in the progeny and only these 20 were *PHR* class and mapped. The failure of 8,465 putatively heterozygous SNPs to map could be explained in relation to paralogy, such that the probe target sites are duplicated in the genome, and are polymorphic between sites. Similar but

non-identical paralogous sequences are likely to result in different annealing with the array probes, producing non-*PHR* cluster patterns. If these apparently heterozygous alleles are duplicated in the *F. iinumae* F1D genome, then they may also be duplicated in *F. vesca* FvH4, even though the duplication is not represented in the current reference genome. One possible way to address this hypothesis would be to recreate the population used to construct the linkage map that anchored the *F. vesca* FvH4 genome and genotype a population subset with the Array and GBS to construct a high density linkage map. Also the FvH4 genomic sequence could be reassembled using the *F. iinumae* linkage map as a comparator. The challenge with the FvH4 reference sequence is that the sequence scaffolds were anchored using an F2 population from an interspecific cross: FV×FB. So the question remains, is the FvH4 sequence correctly assembled?

CHAPTER II

PEDIGREE-BASED ANALYSIS OF FLOWER COLOR VARIATION USING SNP MARKERS FROM THE ISTRAW90 ARRAY

Abstract

This chapter explores the association of flower color traits with genetic markers detected using the IStraw90 strawberry SNP Array in a genome-wide approach. Populations were developed to advance selections for desired flower colors, fruit quality, and flowering cycles, with the ultimate goal of releasing new cultivars. A subset of these breeding lines was used to demonstrate the potential applicability of marker-assisted breeding (MAB) in strawberry with a focus on selection for non-white (NW) versus white (W) flower color.

A diverse population of ornamental hybrids segregating for NW versus W flower color, and for a wide spectrum of hues and color patterns in NW flowers, has been developed. The NW flowers varied in hue from pale pinks and corals to orange reds and scarlet red, and the anthers varied from yellow to darker red. Among the NW flowers, some petals contained darker shades of radial venations and others had petals margins with darker or lighter hues. The population is also segregating for other traits of interest, including flowering habit, fruit quality, and a number of pest and disease resistances. A population subset of 41 individuals called the 'Select Set' was genotyped on the IStraw90 Array. A pedigree-based analysis of the Select Set detected 5,674 segregating SNP markers, thirty-five of which are associated with NW flower color without recombination. Of these 35 markers, 28 are also located on pseudochromosome 5 of the *Fragaria vesca* 'Hawaii 4' reference genome.

Introduction

The project began with a question: why do the fruit of strawberry cultivars contain principally pelargonidin and very little cyanidin? Pursuit of the answer led to additional questions about the genetic controls of fruit and flower color, and to a primary focus on flower color because of its intrinsic horticultural interest as well as its comparative tractability as a subject of genetic research.

RosBREED and the IStraw90 Array

At the outset of my project, I became involved as a Project Associate in the USDA funded RosBREED project (<u>http://www.rosbreed.org/</u>), in which my advisor (Tom Davis) was a Co-P.I. The mission of the project was to bridge the gap between phenotyping and genotyping, and to advance marker-assisted breeding (MAB) in apple, peach, cherry, strawberry, and other members of the Rosaceae family.

As part of the RosBREED Project, we helped to develop standard phenotyping protocols for strawberry (Mathey et al. 2013), and phenotyped a broad range of germplasm and breeding lines. Most significantly, we contributed to the conceptual design and actualization of the IStraw90 strawberry SNP Array (Bassil et al. manuscript submitted). We are evaluating the performance of the IStraw90 SNP Array on diverse breeding and germplasm populations for the detection of segregating SNPs in strawberry, as described in (Bassil et al. manuscript submitted), as well as in Chapter I and in this chapter. Computational pipelines for SNP identification developed by the Davis lab were paramount to the design of the IStraw90 SNP Array (Bassil et al. manuscript submitted). The strawberry SNP Array comprises 95,062 SNPs (Bassil et al. manuscript submitted), in contrast to SNP arrays for other Rosaceae crops; apple (Chagne et al. 2012), peach (Verde et al. 2012), and cherry (Peace et al. 2012), which have no more than 9,000 SNPs. Positive evaluations to-date justify the expectation that the exceptionally large size of the IStraw90 SNP Array will help compensate for the complexities of genotype calling in an octoploid.

The design of the IStraw90 Array, hereafter to be referred to as "the Array", was based predominantly on prior discovery of SNPs on the basis of sequence alignments and variant calling (Bassil et al. manuscript submitted). The design of the Array was based on three categories of markers (Table 2.1): 1) octoploid- based SNPs identified by discovery in an octoploid germplasm panel of 20, that included the three founders of the populations described in this chapter; 2) F1Dsnps - based on discovery in diploid *F. iinumae* (see Chapter I); and III) a speculative codon-based approach, which was not based on discovery, but on the third position nucleotide wobble of the amino acid proline within gene regions as annotated in the *F. vesca* FvH4 reference sequence (Shulaev et al. 2011). The octoploid-based category of markers was further subdivided into eight categories based on marker type, four of which were designed to identify segregation at the subgenomic level. The latter were called 'haploSNPs' (SnpSnp, IndelSnp, SnpinIns, SnpinDel), while the remaining four were designed to target di-allelic (Snp, Insertion, Deletion) or multi-allelic (mSnp) polymorphisms (Table 2.1).

The RosBREED IStraw90 SNP Array (Bassil et al. manuscript submitted) is a significant step towards reducing genotyping to manageable and hopefully attractive levels for MAB. With the IStraw90, the likelihood of finding robust marker-trait associations and quantitative trait loci in a genome wide scan was promising, offering an irresistible paradigm shift compared to onemarker-at-a-time approaches with their concomitant multitudes of PCR reactions and gel-

electrophoresis.

Table 2.1: Counts of IStraw90 Array SNPs by category. The primary categories are the octoploid-based, *F. iinumae* diploid-based F1Dsnps, and codon-based SNPs.

Marker name	Count	Description
Snp	63,263	SNP with two alternate alleles
mSnp	1,761	SNP with four alternate alleles
ins	4,615	An insertion
del	4,913	A deletion
SnpSnp	7,092	Subgenome-specific SNP adjacent to a marker SNP
indelSnp	1,176	Subgenome-specific indel adjacent to a SNP
SnpinIns	2,007	SNP inside a subgenome-specific insertion (insertion relative to F. vesca reference)
SnpinDel	836	SNP inside a subgenome-specific insertion (deletion relative to <i>F. vesca</i> reference)
Octoploid-based total	85,663	Discovered in octoploid germplasm panel
F1Dsnp	3,751	Discovered in F1D
Codon-based	5,648	Non-discovery based SNP candidates
Array Total	95,062	All SNPs on the Array

Marker-Assisted Breeding

Advancing marker-assisted breeding (MAB) of *Fragaria* ×*ananassa*, the principal strawberry of commerce, has been at the core of my applied research and breeding objectives. Marker-assisted breeding requires a genotyping platform for construction of a linkage map, as well as phenotypic data for identification of quantitative trait loci (QTL). An early feasibility study concluded that MAB would be cost prohibitive in strawberry, and more labor intensive than traditional breeding (Luby et al. 2001). But with the advent of next generation sequencing (NGS) platforms, the cost of sequencing has dramatically declined in the last ten years, from \$8,000/Mbps to \$0.10/Mbps in 2012 (Poland et al. 2012), opening opportunities for sequence-based genotyping strategies such as genotyping-by-sequencing (GBS) (Elshire et al. 2011, Poland et al. 2012), and for sequence-based, single nucleotide polymorphism (SNP) discovery. The expense and labor intensity of phenotyping has yet to be overcome, although inroads are

being made with imaging and computation software (Eberius 2009). Increasingly, streamlined pipelines for bioinformatics are being developed and improved to make effective application of MAB a foreseeable reality (Bink et al. 2012, Poland et al. 2012, Rosyara et al. 2013). Although MAB of strawberry is particularly challenging because of its octoploid genome, the use of state-of-the-art genotyping platforms such as the Array, GBS, and others promise to make MAB in strawberry practical in terms of cost and effort.

Linkage Maps - Setting the stage for MAB, a number of linkage maps for the octoploid strawberry have been published recently: (Rousseau-Gueutin et al. 2008, Spigler et al. 2008, Weebadde et al. 2008, Sargent et al. 2012, Zorrilla-Fontanesi et al. 2012, Isobe et al. 2013). Marker loci densities of 0.5 (Lerceteau-Kohler et al. 2012) and 0.8 per cM (Isobe et al. 2013) were achieved using PCR-based markers. Previous studies with other crops have recommended marker loci densities of 1 per cM or less to define a QTL with sufficient precision for use in MAB. Genome resolutions using current genome wide scan technologies are expected to easily exceed the target marker loci density of 1.0 per cM.

Quantitative trait locus (QTL) analyses - QTL analyses employ statistical methods to discover links between traits and marker loci in a mapping population segregating for the trait(s) of interest. Using two of the previously cited *F.* ×*ananassa* mapping populations: 'Capitola' x 'CF1116' (Rousseau-Gueutin et al. 2008), and '232' × '1392' (Zorrilla-Fontanesi et al. 2011), the Capitola' × 'CF1116' population (Rousseau-Gueutin et al. 2008) was phenotyped for 19 fruit quality traits, which resulted in the identification of 87 QTL. The '232' × '1392' population (Zorrilla-Fontanesi et al. 2011) was phenotyped for 17 agronomical and fruit quality traits, resulting in identification of 33 QTLs (Zorrilla-Fontanesi et al. 2011), and was also later phenotyped for 48 volatiles in fruit, which resulted in an additional 70 QTLs (Zorrilla-Fontanesi et al. 2012).

Using pedigree based analysis and a combination of SSR and SNP markers, six QTLs for fruit size were located in cherry, another member of the Roseaceae family, confirming two QTLs previously identified in a single mapping population and discovering four new QTL (Rosyara et al. 2013). In the cherry study, pedigree relationships were visualized using Pedimap (Voorrips et al. 2012), and FlexQTL was used to discover QTLs (Bink et al. 2008). This work in cherry is highly relevant to my project because my approach is also pedigree-based, as distinct from the single population-based analyses previously conducted on strawberry as described above.

Plant pigments

The colors of flowers and fruit are the result of flavonoids (which include anthocyanins), carotenoids, and betalains (Mol et al. 1998). The betalains occur in only the Caryophyllales family and do occur simultaneously with anthocyanins (Mol et al. 1998). The colors and hues are further modified by co-pigmentation, pH, and cell shapes (Mol et al. 1998) and complexes with metal ions (Tanaka1 et al. 2008). The major pigments in Rosaceae flowers and fruit are usually the result of anthocyanins (Lin-Wang et al. 2010), and in strawberry fruit the anthocyanins are pelargonidin and cyanidin (Mahoney 2007, Wang et al. 2007, Mahoney et al. 2009).

Strawberry fruit

The strawberry is an accessory fruit composed of a swollen flower receptacle (the fleshy part) and seed-like achenes, which are the true botanical fruit (Perkins-Veazie 1975, Suutarinen et al. 1998, Fait et al. 2002). The achenes are derived from uni-carpellate pistils, and the

hardened pericarp encloses the seed (Perkins-Veazie 1975, Aharoni et al. 2002, Fait et al. 2002). In common usage and in this thesis, the swollen receptacle along with the achenes, are together referred to as the strawberry fruit.

Octoploid strawberry - The octoploid strawberry F. \times ananassa genome (2n=8x=56) has a 1C genome size of 780-800 million base pairs (Mbp) (Davis et al. 2007). Fragaria × ananassa arose in France in the 1700's from an accidental hybridization between a white-fruited Chilean strawberry F. chiloensis ssp. chiloensis and a wild North American species, F. virginiana ssp. virginiana (Darrow 1966). Importantly, considerable diversity exists within both F. chiloensis and F. virginiana, each of which comprises four subspecies (Hancock et al. 2000). Thus, these wild species offer a rich germplasm pool for breeding (Hancock et al. 1993, Hancock et al. 1993, Hancock et al. 2010, Stegmeir et al. 2010). Both the white- and red-fruited forms of the South American F. chiloensis have been used in breeding and white-fruited cultivars of F. chiloensis are prevalent in Chile (Hancock et al. 2001, Carrasco et al. 2007). The white-fruited forms of F. chiloensis contain only trace levels of anthocyanins (Saud et al. 2009), although the achenes are red, while the red fruited form lacks the high cyanidin trait of interest to my research (Mahoney 2007, Mahoney et al. 2009). A source for the high cyanidin trait was found in North American F. chiloensis ssp. lucida (FRA1691) germplasm accession from Oregon (Mahoney 2007, Mahoney et al. 2009).

<u>Diploid strawberry</u> - There are currently twelve recognized diploid strawberry species (Hummer et al. 2011), one less than the previously considered thirteen (Folta et al. 2006, Staudt 2009) because *F. yezoensis* has been sub-classified under *F. nipponica* (Hummer et al. 2011). Many of the diploid species are red-fruited, but there are a number of exceptions including white-fruited *F. nilgerrensis* ssp. *nilgerrensis*, white-to-pink *F. daltoniana*, white-fruited *F.*

pentaphylla (Hummer et al. 2011), and a few *F. vesca* ssp. *semperflorens* varieties that have yellow fruit (Darrow 1966). In addition, *F. tibetica* forma *alba*, a tetraploid, is also white- fruited (Hummer et al. 2011). The reference sequence for strawberry, based on yellow-fruited *F. vesca* ssp. *semperflorens* "Hawaii 4' (Shulaev et al. 2011). *F. vesca*, *F. iinumae*, and possibly a third as-yet-to-be-identified diploid are considered ancestral to the octoploid strawberry (Folta et al. 2006, DiMeglio et al. 2014).

Strawberry flowers

Strawberry flowers are normally white. The prior introgression of a "colored flower" trait from a wild source into a cultivated background (Ellis 1962) has opened an opportunity for breeders to add an ornamental quality to cultivated strawberry as the result of an interspecific cross of F. ×ananassa (previously known as F. grandiflora) with Potentilla palustris. Fragaria grandiflora (2n =8x=56) 'Sans Rivale' $\times P$. palustris Scop (2n=6x=42) resulted in hybrids with pink flowers and a chromosome number of 2n = 49 (Ellis 1962). 'Sans Rivale' was an everbearing, very vigorous and large-fruited variety developed in 1937 (Darrow 1966). Potentilla palustris has large, spongy receptacles (Ellis 1962). Fragaria 'Frel', the first introduced pink-flowered ornamental was developed from this original cross, with five back crosses with F. grandiflora as a female, and thus considered to be 96% Fragaria (Ellis 1991). The introduction of pink-flowered cultivar 'Frel' (Ellis 1991), later known as 'Pink Panda', which has a continuous flowering habit albeit with small fruit, has inspired the development and continuing release of new ornamental strawberry cultivars with pink flowers, such as 'Serenata' (Ellis 1994), 'Rosalyne' (Khanizadeh et al. 2002), 'Roseberry' (Khanizadeh et al. 2002), 'Lipstick' (Northcrop name, verbal communications), 'Red Ruby', patented as 'Franor' (Bittner 2001), and 'Tarpan' (ABZSeeds 2014). I am taking advantage of this prior resource, which I have enhanced by identifying and utilizing new sources of hue variants to combine with a pink-flowered accession. Discovery of molecular marker associations for non-white (NW) versus white (W) flower color, for variant hues, and for variant fruit pigment composition will facilitate MAB of new cultivars with enhanced ornamental qualities and enhanced fruit quality. The presence of a strong ornamental industry, which is the single largest agricultural sector in NH, highlights an opportunity for developing locally adapted ornamental cultivars targeting homeowners, landscapers, and small scale producers.

Strawberry fruit and flower pigments

Cyanidin and pelargonidin are the two principle pigments in the fruit of strawberry. The absolute and relative contents of cyanidin and pelargonidin influence the hues of both flowers and fruit, with cyanidin imparting a pinkish component and pelargonidin an orange component. Cyanidin was reported to have twice the anti-oxidant potential of pelargonidin (Wang et al. 1997, Pietta 2000). Cyanidin and pelargonidin levels in strawberry fruit of various diploid and octoploid (wild and cultivated) species, and in the flowers and fruit of the F1 progeny of a pink-flowered ornamental \times white flowered cultivar cross ('Bountiful' \times 'Pink Panda') have been quantified (Mahoney 2007).

It had been reported that the fruit of strawberry cultivars contained low levels of cyanidin in comparison to pelargonidin (Nyman et al. 2001, Mahoney 2007, Wang et al. 2007). In contrast the fruit of an unidentified accession of diploid *F. vesca* contained equal amounts of cyanidin and pelargonidin (Sondheimer et al. 1956) and these finding are consistent with Mahoney (2007). However in a survey of wild accessions (Mahoney 2007, Mahoney et al. 2009) identified an accession of octoploid *F. chiloensis ssp. lucida* with high fruit cyanidin content. Contrastingly, in the flowers of 'Bountiful' × 'Pink Panda' (B×PP) population segregating for NW (with hues from light to medium pink) versus W flower color, Mahoney (2007) found only cyanidin and no detectable levels of pelargonidin in the NW flowers. These findings led to four questions. 1) Why was there only cyanidin in the B×PP pink flowers? 2) Could a red flowered strawberry ornamental be developed and would the red flowers contain both cyanidin and pelargonidin? 3) Could the trait of high cyanidin content in the fruit be introgressed from the high cyanidin *F. chiloensis* ssp. *lucida* accession into the cultivated strawberry? 4) Could we develop markers to identify or predict the qualitative trait of color (presence/absence, where absence = white) and the quantitative trait of variable hue in relation to pigment composition?

Anthocyanin pathway

The anthocyanin pathway is controlled by structural and regulatory genes, which affect qualitative (presence/absence) and quantitative variation in color intensity and hue.

Anthocyanin biosynthesis structural genes - The basic anthocyanin biosynthetic pathway for the synthesis of cyanidin and pelargonidin in plants is well understood (Holton et al. 1995, Moss 2001), as illustrated in Figure 2.1. The pathway begins with the biosynthesis of tetrahydroxychalcone, mediated by chalcone synthase (CHS), from the condensation of a product of the phenyl-propanoid pathway, p-coumaroyl Co-A, and 3x of malonyl-CoA (Almeida et al. 2007). Tetrahydroxychalcone is then converted to naringenin by chalcone isomerase (CHI). The lack of specificity for substrates and the competition between the enzymes for common substrates results in the availability of multiple paths for the same intermediate (Holton et al. 1995). The pathway can branch three ways at naringenin to produce apigenin via flavone synthase (FS), and/or eriodictyl via flavonoid 3'-hydroxylase (F3'H), and/or dihydrokaempferol via flavonone 3-hydroxylase (F3H). Dihydroquercetin may be produced via F3H from eriodictyl and/or from F3'H from dihydrokaempferol. Dihydroflavonol 4-reductase (DFR) reduces dihydrokaempferol to produce leucopelargonidin, and reduces dihydroquercetin to produce leucocyanidin. Flavonol synthase (FLS) oxidizes the dihydroflavonols to produce kaempferol and quercetin. The F3'H enzyme competes with DFR and FLS (Holton et al. 1995) for substrates, and kaempferol (a flavonol), naringenin (a flavanone), and epigenin (a flavone) all serve as substrates for F3'H (Moss 2001), competing with dihydroquercetin. Leucocyanidin and leucopelargonidin are both synthesized from dihydrokaempferol, but leucocyanidin can also be synthesized from dihydroquercetin. Leucocyanidin and leucopelargonidin are converted subsequently to cyanidin and pelargonidin by leucoanthocyanidin oxgenase (ANS) and/or to the proanthocyanidin pathway to produce catechin and afzelechin, respectively, bv leucoanthocyanidin reductase (LAR). Cyanidin and pelargonidin may also be diverted to the proanthocyanidin pathway via anthocyanidin reductase (ANR) (Almeida et al. 2007) or to the final step of the anthocyanidin pathway where they are converted to cyanidin-3-glucoside and pelargonidin-3-glucoside during glucosylation mediated by 3-O-glucosyltransferase (3GT) (Pourcel et al. 2010) and transferred in the vacuoles via glutathione S-transferase (GST) (Pourcel et al. 2010).

Tetrahydroxychalcone is yellow, whereas naringenin is colorless (Holton et al. 1995). Kaempferol and quercetin act as co-pigments to intensify flower color and generally shift it towards blue (Brugliera et al. 1999). The intermediate products are colorless until the glycosylation of the anthocyanidin by 3GT to anthocyanidin 3-glucosides (Holton et al. 1995), accompanying the transfer of the anthocyanidin to the vacuole by GST (Pourcel et al. 2010). Anthocyanin biosynthesis regulatory genes - The r and c1 families of regulatory genes in maize, analogous to an1, an2, an4 and an11 in petunia, control the transcription of all the structural genes of the anthocyanin pathway (Quattricchio et al. 1998). The petunia *JAF13* is orthologous to the maize r genes, which encode bHLH (basic helix-loop-helix) proteins, and the c family, which encodes MYB transcription factors (Quattricchio et al. 1998). In a comparison of R2R3 MYB transcription factors in Rosaceae, Lin-Wang et al. (2010) concluded that *MYB1* and *MYB10* are alleles of each other in an apple red × white flesh segregating progeny.

<u>Flower color</u> - Flower color has been modified in numerous plants using traditional breeding as well as molecular approaches. The suppression of *CHS* gene expression in petunia, chrysanthemum, carnation and rose (Gutterson 1995) has resulted in white flower color. A modification of *CHS* gene expression impacted the flower color intensity in *Petunia* ×*hybrida* (Hanumappa1 et al. 2007), but did not produce white flowers. In petunia, high levels of cyanidin derivatives accumulate only in accessions that possess F3'H activity but that lack flavonoid 3'5'-hydroxylase (F3'5'H) (not shown in Figure 2.1) and FLS activity (Holton et al. 1995). The *F3'H* transgene was introduced into a homozygous recessive petunia with pale lilac flowers which resulted in a F3'H transgenic line of petunia with highly pigmented pink flowers and anthers (Brugliera et al. 1999). Of regulatory gene products, transcription factors such as bHLH alone or in combination with MYB transcription factors have been found to control pigmentation in flowers (Quattricchio et al. 1998).

<u>Strawberry anthocyanin genes</u>

Although the anthocyanin biosynthetic pathway has been described in generalized form (Figure 2.1), in strawberry its specific details continue to be refined (Halbwirth et al. 2006, Almeida et al. 2007).

Gene characterization in *Fragaria* ×*ananassa* – Gene names in *Fragaria* ×*ananassa* are prefixed with '*Fa*'. All of the pathway structural genes including *FaCHS1*, *FaCHS2*, *FaCHS3*, *FaCHS5*, *FaCHI*, *FaANS*, *FaANR*, *FaDFR*, *FaLAR*, *FaFGT* (aka *3GT*), *FaFHT* (*F3H*), and *FaFLS* have been sequenced and the relative transcriptional activities of each have been characterized and compared in roots, leaves, flower petals and ripening fruit of 'Queen Elisa' and 'Korona' (Almeida et al. 2007). *CHI*, *CHS*, and *ANS* gene sequences have also been isolated from 'Elsanta' as cDNA (Aharoni et al. 2002), *DFR* from 'Chandler' (Moyano et al. 1998), and *FaGT1*, *UFGT* (*FaGT1* through *FaGt7*) from 'Elsanta' (Griesser et al. 2008). In addition, phenyl-propanoid pathway genes (*FaPAL*, *FaC4H*, and *Fa4CL*) have been sequenced and their transcriptional activities have been similarly characterized (Almeida et al. 2007). The regulatory transcription factor *FaMYB1* has been sequenced from *F*. × *ananassa* 'Elsanta' and characterized in strawberry, as well as in tobacco and yeast using transformants (Aharoni et al. 2001).

Gene characterization in *Fragaria chiloensis* –Transcriptional activity levels of whitefruited *F. chiloensis* ssp. *chiloensis* structural genes of the phenyl propanoid pathway (*PAL*, *C4H*, *4CL*) and the anthocyanidin pathway (*CHS1*,*CHS2*,*CHS3*, *CHS5*, *CHI*, *F3H*, *DFR*, *ANS*, *FGT* (aka *3GT*), and one regulatory gene (*MYB1*) were compared to their counterparts in *F. ×ananassa* 'Chandler'(Saud et al. 2009). Transcript levels in the ripening strawberry fruit were generally lower in the white-fruited *F. chiloensis* compared to *F. × ananassa* (Saud et al. 2009). Transcript levels of *CHS2, CHS3, CHI, F3H*, and *FGT* were minimally expressed in *F. chiloensis* (Saud et al. 2009). A similar comparison of transcript levels of structural genes (*PAL, C4H, 4CL, CHS, CHI, F3H, DFR, ANS, UFGT, FLS, LAR, ANR*) was made on ripening fruit of *F. chiloensis* ssp. *patagonica* (red fruited) to white-fruited *F. chiloensis* ssp. *chiloensis* (Moyano et al. 1998). Transcript levels of anthocyanidin pathway structural genes were generally higher in the ripening fruit of *F. chiloensis* ssp. *patagonica* fruit of *F. chiloensis* ssp. *patagonica* (red fruited) to white-fruited *F. chiloensis* ssp. *chiloensis* (Moyano et al. 1998). Transcript levels of anthocyanidin pathway structural genes were generally higher in the ripening fruit of *F. chiloensis* ssp. *patagonica* particularly at the ripe stage (Moyano et al. 1998). Transcript levels of the phenyl-propanoid pathway (*PAL, C4H, 4CL*) gene generally tracked together downward with degree of ripening (Moyano et al. 1998).

FcMYB1, an F. chiloensis ortholog of *FaMYB1*, was isolated from white fruited *F. chiloensis* ssp. *chiloensis* and its impact on the activity of structural genes *F3H*, *DFR*, *ANS*, *UFGT* (aka *3GT*), *LAR*, and *ANR* were determined. The transient suppression of *FcMYB1* using RNAi caused a slight reddening of the fruit and a most significant down regulation of *LAR* and *ANR* gene expression.

<u>Gene characterization in diploid strawberry</u> - Intron-containing segments of anthocyanin pathway genes *CHS*, *CHI*, *F3H*, *DFR*, and *ANS* and *RAN* (a *Del*-like regulatory gene) were cloned from *F. vesca* and sequenced (Deng et al. 2001) and the complete sequence of *F3'H* was cloned from *F. vesca* ssp. *americana* (Mahoney unpublished). Subsequently, the complete sequences of these genes have been revealed in the *F. vesca* 'Hawaii 4' reference genome (Shulaev et al. 2011).

In *F. vesca*, there are yellow and red fruited accessions and varieties. In two F2 mapping populations *F. vesca* \times *F. vesca* (DN1C \times YW) and *F. vesca* \times *F. nubicola* (YW x FRA520) (Deng et al. 2001), which were segregating for red versus yellow fruit, anthocyanin candidate genes were mapped in an effort to identify a gene-trait association between an anthocyanin

pathway structural or regulatory gene and the color locus (*c*). Co-segregation without recombination between the *c* locus and the *F3H* gene was reported (Deng and Davis, 2001), suggesting that a mutation in the *F3H* gene was responsible for the yellow fruit trait. More recently, recombination between the *c* locus and the *F3H* gene on LG1 was detected (Shields and Davis unpublished), undermining the hypothesis of identity between *c* locus and *F3H*.

Segregating populations for flower color and fruit quality have been developed with the objectives of 1) understanding the genetic control of cyanidin and pelargonidin pigment levels in flowers and fruits, and 2) developing cultivars adapted to the Northeast region for the ornamental market. A pedigreed 'Select Set' of 41 members was chosen to include the three parental founders and a sampling of floral NW and W members and the spectrum of fruit pigment composition from each of the four generations. The NW members were chosen to represent the diversity of flower color and hue (variant colors and color patterns). The 'Select Set' of 41 individuals was genotyped on the Phase 1 test of the IStraw90 Axiom Array (Bassil et al. manuscript submitted). Long-term goals are to advance MAB and to introduce NW flower color and desirable flower hues and fruit pigment composition traits into cultivated strawberry backgrounds in order to develop a marketable collection of day-neutral cultivars with a palette of flower hues and desirable fruit size and quality. Herein, is described the first study of marker-trait association for flower color in strawberry.

Figure 2.1: Anthocyanin biosynthetic pathway. Enzyme abbreviations: CHS (chalcone synthase); CHI (chalcone isomerase); FS (flavone synthase); F3H (flavonone 3-hydroxylase); FLS (flavonol synthase); F3'H (flavonoid 3'-hydroxylase); DFR (dihydroflavonol 4-reductase); LAR (leuco-anthocyanidin 4-reductase); ANR (anthocyanidin reductase); ANS (leucoanthocyanidin oxygenase); 3GT (anthocyanidin 3-*O*-glucosyltransferase).

Materials and Methods

Plant Materials

Three population founders, FC1, FC2, and FC3 were selected as crossing parents based upon their desirable traits. Founder FC1, an accession of *F. chiloensis* ssp. *lucida*, has W flowers and is the source of genes influencing the hue and cyanidin composition of fruit (Mahoney 2007, Mahoney et al. 2009). FC2, an *F.* ×*ananassa* derivative, presumably of 'Pink Panda', with pink-flowers, is the source of the genetic determinant(s) for NW flower color. FC3, an accession of *F. virginiana* ssp. *glauca*, has W flowers and is the source conferring day-neutrality. FC1 was obtained from the NCGR germplasm collection, while FC2 and FC3 were collected by Tom Davis in 2001, from cultivated and wild locations, respectively, near Prince George, British Columbia. The three founders were used to generate the Closed Pedigree Set consisting of four generations. Select individual members of the Closed Pedigree Set based on flower color were crossed with cultivars in phase 2 to generate hybrids with desirable color and fruit quality. Breeding lines were intercrossed towards the goal of increasing cyanidin content in the fruit.

Generating hybrids

<u>Making a cross</u> – A flower on a plant to serve as the female (i.e., pollen recipient) was selected just before anthesis, at the bud stage but just before opening. A flower on a plant to serve as the male (i.e., the pollen donor or pollen parent) was selected at anthesis when the anthers were bursting with pollen, optimally in late morning on a sunny day. The recipient flower was emasculated, and the pollen-bearing anthers from the pollen parent flower were
brushed onto the recipient flower. The pollinated recipient flower was tagged and isolated with a small polyester mesh bag tightened with a draw-ribbon around the pedicel to prevent chance extraneous pollination by visiting insects.

<u>Harvesting and storing achenes</u> - The fruit were harvested approximately 30-50 days post pollination, depending on the season. For harvesting of achenes, a fruit was cut open, the flesh was carved-out, and the fruit exterior was pressed epidermis side up onto recycled non-craft paper and allowed to dry for a few days. The achenes were harvested by rubbing them off the paper and cleaning off debris by manually vibrating the seeds on a clean sheet of paper. The harvested seeds were stored in small envelopes within a zip-lock bag or plastic box and refrigerated at 4 C.

<u>Seed propagation with potting media</u> – Achenes/seeds selected for planting were refrigerated for a minimum of 2 weeks, providing a measure of vernalization in the event that some of the seeds might not germinate at all or not very well without such treatment.

The procedure that follows was intended to disinfect achenes from pests or microbes. The seed starting mix was moistened and placed in an autoclave tray and covered with foil and autoclaved using liquid autoclave settings. The cleaned seeds were placed in labeled 1.5 ml micro-centrifuge tubes, then soaked for 10 minutes with 200 ml of aqueous using Tween 80 at 0.05%. The 0.05% Tween 80 solution was removed. The seeds were then sanitized by adding 200 μ l of 30% bleach solution (Chlorox liquid bleach, 5.25% sodium hypochlorite) to each tube and agitated for 10 minutes at 30-50C. The bleach solution was removed and the seeds were rinsed three times with dH2O, again 200 μ l each time. The last rinse was used to remove the seeds from the tubes, by mixing to suspend seeds and dumping the contents onto a paper towel.

The seeds were planted in the seed-starting mix in seedling trays or 4" pots and covered with fine-powdered sterile peat-moss to prevent damping off.

The seeds were then germinated using one of two options under grow-lights or in the greenhouse: Under the grow lights option, the seedling trays or pots were covered with a clear slotted (for ventilation) plastic cover. At 7-10 days post-planting, the cover was taken off and grow lights were turned on for a daily photoperiod of 16 hours. The mix was sprinkled with a little more peat moss periodically. With the greenhouse option, the seedling trays or pots were placed under mist on the greenhouse mist bench and regularly checked for germination. Once seedlings were established, the pots were removed from the mist bed but maintained elsewhere in the misted greenhouse until ready to transplant.

DNA isolation

One sample containing three furled leaves of approximately 50-100 mg fresh weight from each individual were freeze-dried and shipped to N. Bassil group at the National Germplasm Repository, where the DNA was isolated using the E-Z® 96 Plant DNA kit (Omega bio-tek, Inc) following (Gilmore et al. 2011); the same protocol as was followed for *F. iinumae* as described in detail in Chapter I.

Phenotyping for presence/absence of flower color

The presence or absence of flower color (pigmentation), a qualitative trait, was determined visually and was classified as NW or W. To be categorized as W, the flower petals had to be entirely white. For example, a flower with otherwise white petals but with colored rays or venations was considered NW.

Phenotyping for flower and fruit pigmentation

The phenotyping of flower and fruit pigment composition was performed by High Performance Liquid Chromatography (HPLC) for contents of pelargonidin and cyanidin. The preparation of the fruit for analysis, and the HPLC analysis itself were performed following a previously developed protocol (Mahoney 2007, Mahoney et al. 2009). The protocol reported below is reproduced verbatim from (Mahoney 2007) with only minor edits for clarification and with the following exceptions: 1) the fruit was frozen at -20C and was not lyophilized; instead a wedge of fruit sample was cut and weighed. Upon addition of the 7 ml of 2N HCl, the samples was vortexed until homogenized; and 2) 'Earliglow' instead of 'Jewel' was used as an external standard. The assay of flowers was performed using 0.2 g fresh petals and using 5 ml instead of 7 ml of 2N HCl for hydrolysis. The moisture content of the petals was assumed to be comparable to that of rose, at 65% (Schmitzer et al. 2010). The protocol for the sample preparation and HPLC analysis reproduced verbatim from Mahoney (2007) is as follows:

<u>Fruit sample preparation for anthocyanidin assay - hydrolysis of anthocyanins</u> (Mahoney 2007). The fruit was pulverized (Wang et al. 2003) to achieve a uniform composite sample. The acid hydrolysis process was performed using aqueous 2N HCl (Durst et al. 2001), as opposed to the use of 2N HCl in methanol (Nyman et al. 2001), to avoid use of highly hazardous methanol at elevated temperatures and in proximity to non-explosion proof electrical devices. Each 0.5 g sample of lyophilized strawberry fruit was mixed with 7 ml of 2N HCl in a 15 ml polypropylene centrifuge tube (VWR SuperClearTM Catalog #21008), hydrolyzed at 90°C for 50 minutes (Nyman et al. 2001) in a Nitrogen EvaporatorTM 111 (Organomation Associates, Inc) used as a hot water bath, and then cooled in a separate cold tap-water bath for 5 minutes. The hydrolyzed samples were spun for 20 minutes in an Eppendorf 5804R centrifuge at 15,500 xg and 4°C. The centrifuged samples were filtered, using syringe-adapted filter housings with F6801 Sigma-Aldrich 100 µm mesh nylon fabric, to recover the liquid extract containing the anthocyanidins.

Extraction of anthocyanidins (Mahoney 2007) - The procedure used to extract the anthocyanidins was patterned after those previously described (Rodriguez-Saona et al. 2001, Wang et al. 2003, Wang et al. 2003), with modifications as indicated below. Sep-Pak[®] C18 cartridges (Waters Corp, Ireland) were activated with 2 ml of 0.01% HCl in methanol, but the additional rinses of deionized water (Rodriguez-

Saona et al. 2001, Wang et al. 2003) or formic acid (aqueous) (Wang et al. 2003) were not employed. Each supernatant sample was poured into a Sep-Pak[®] C18 cartridge to bind the anthocyanidins, then the sugars and starches were eluted with 10 ml of 3% formic acid (aqueous). The anthocyanidins and other phenolic compounds were recovered from the C18 Sep-Pak[®] cartridges with 2.5 ml acidified methanol containing 0.01% HCl (Rodriguez-Saona et al. 2001).

The recovered anthocyanidins were then filtered with a 0.2 μ m syringe filter, in lieu of the 0.45 μ m filter (Wang et al. 2003), to prolong the life of the HPLC separation column. Sample aliquot volumes of 750 μ l were transferred to 1.5 ml HPLC vials for analysis. In order to minimize decomposition of the anthocyanidins, the processed samples were immediately analyzed by HPLC, or held in a -20°C freezer before warming to room temperature for 15 to 20 minutes before analysis by HPLC. The purified samples were stored at -80°C according to Rodriguez-Saona and Wrolstad (2001), who recommended storage of purified samples at less than -15°C, preferably less at -70°C.

<u>Preparation of anthocyanidin standard solutions</u> (Mahoney 2007) – "Standard solutions needed for calibration of the HPLC for assays were prepared from concentrated master stock solutions. The master solutions were prepared by dissolving certified HPLC grade powder standards (Indofine Chemicals, Hillsborough NJ) of pelargonidin chloride and cyanidin chloride in acidified methanol (0.01% HCl) to make master solutions. The master solutions were made at a concentration of 1000 μ g/g in acidified methanol as follows: the powder standards were weighed (scale accuracy of four decimal places) and then the required amount of acidified methanol was used to police the powder standard into a dark colored vial. The required amount of acidified methanol was determined as follows:

Y mls of methanol = $\underline{X \text{ gms of powder standard} \times \text{purity of standard}}_{(\text{density of methanol} \times 1000 \, \mu\text{g/g})}$

The purity of the powder standards was obtained from the certificates of analysis (COA): Pelargonidin COA = 0.998; Cyanidin COA = 0.972. The density of methanol (0.7875 g/ml) was obtained from the manufacturer's technical data sheet.

Standard solutions with concentrations of 10, 50, 90, 100, and 150 μ g/g of cyanidin and pelargonidin chloride were each made directly from the master solutions For instance, to make a standard solution concentration of 10 μ g/g of acidified methanol, 10 μ l of the master batch was added to 990 μ l of acidified methanol. Aliquots of the standard solutions were stored at -20°C.

Using freshly made standards, the HPLC was calibrated to develop a calibration curve for 5 μ l sample injections. Aliquots of anthocyanidin extract of cultivar 'Jewel' fruit, prepared as described earlier and stored at -80°C, were used as an external standard for all assays in Phase 3, to assure run-to-run repeatability. Cyanidin and pelargonidin were identified by comparing the retention times of the standards with those of the strawberry fruit extract.

<u>High Performance Liquid Chromatography method</u> (Mahoney 2007) – The separation and quantification of cyanidin and pelargonidin were conducted following a modified protocol (Miyazawa et al. 1999) with a Hewlett Packard Series 1100

HPLC equipped with a Diode Array Detector. A reverse-phase Nova-Pak[®]C18 column 150 x 3.9 mm with 4 μ m particle size equipped with a Nova-Pak[®]C18 20 x 3.9 mm guard column (Waters Corp, Ireland) (Wang et al. 2003) was used for the separation of cyanidin and pelargonidin. Due to its smaller size (lower cost) and corresponding lower chemical and sample volume requirements, this configuration was preferred to a commonly used reverse-phase C18 250 x 4.6 mm ODS (Miyazawa et al. 1999, Durst et al. 2001).

The photodiode array was set to scan the range of 240 to 570 nm with detection at 320, 350 and 528 nm, similar to Wang et al. (2003), whose scan was set at 240 to 550 nm with detection at 320, 350 and 510 nm, as compared with single point detection at 520 nm (Durst et al. 2001), or 532 nm (Miyazawa et al. 1999)

The temperature of the columns was maintained at 30° C to operate above fluctuations in the room temperature which might impact results, in contrast to the use of ambient temperature (Durst et al. 2001), 20° C (Wang et al. 2003), or 40° C (Miyazawa et al. 1999). Cooling the column was not an option with the utilized HPLC system.

The solvents chosen for mobile phases A and B were formic acid (aqueous) and 100% methanol, respectively, (Miyazawa et al. 1999), in contrast to Wang et al.(2003) mobile phases A 2.5% formic acid (aq) and B (acetonitrile) or mobile phases A (acetonitrile) and B (10% acetic acid, 5% acetonitrile, and 1% phosphoric acid) (Durst et al. 2001) to coincide with the chemicals used in the sample preparation and thus minimize the variety of chemicals required.

The mobile phase A concentration of formic acid was reduced to 0.3% v/v from 6.9% v/v (1.5 molar)(Miyazawa et al. 1999) or from 2.5% v/v (Wang et al. 2003) in order to minimize corrosion of the HPLC plumbing system and to extend the life of the column, as well as to minimize use of chemicals, while maintaining an acidic pH for pigment stability and maximum absorption (Cabrita et al. 2000). The mobile phase B methanol was diluted to 95% v/v to reduce gas bubbles in the column at the point of mixing of the two mobile phases.

Isocratic elution as opposed to gradient elution was chosen to maintain steady state and thus minimize the run cycle time to 15 minutes. The mobile phases were optimized to 52% as mobile phase A (0.3% formic acid) and 48% as mobile phase B (95% methanol) in contrast to (Miyazawa et al. 1999) compositions of 14% A containing 1.5 mol/l (6.9%) formic acid and 86% B (100% methanol) and in contrast to gradient elution and alternative mobile phase solvents as described above (Wang et al. 2003). The mobile phase total flow was reduced to 0.7 from 1.5 ml/min (Miyazawa et al. 1999) based on the smaller column size and from 1.0 ml/min (Wang et al. 2003) based on sample peak shape. The initial volume of the sample injection was 20 μ l (Phase 1) in accordance with Wang et al.(2003) much less than the 50 μ l used by Durst and Wrolstad (2001) or 100 μ l by Miyazawa et al.(1999). The volume of the sample injections was later optimized to 5 μ l (Phases 2 and 3) to reduce the load on the columns, with the intent of reducing the potential for overload and improve peak shape.

A volume of 5 μ l of the prepared anthocyanidin samples, were auto-injected into an isocratic 0.7 ml/min elution stream containing 52% mobile phase A (0.3% formic acid) and 48% mobile phase B (95% methanol).

Genotyping

The SNPs were genotyped (Bassil et al. manuscript submitted) using Affymetrix GTC and SNPolisher bioinformatics software. The quality of the genotyping results relied on categorization of cluster plots according to the Affymetrix rating system. The genotype calls for each marker was represented as a cluster plot and the quality of the plots was categorized into six classes (Chapter I, Figure 1.5) as follows. 1) In the highest quality class, the Poly High Resolution (PHR) class, cluster plots are required to contain no more than three highly distinct clusters, including both of the expected homozygous genotyping clusters. 2) The Call Rate Below Threshold (CRBT) class contains both of the expected homozygous genotyping clusters, but is considered lower quality because of dispersed sample points within clusters. 3) In the Mono High Resolution (MHR) class, there are less than two occurrences of the minor allele. 4) The No Minor Homozygous (NMH) class displays only two clusters and lacks one of the expected homozygous clusters. 5) The Other (Oth) class has distinct clusters but they are shifted off center and/or the individual samples dots within the three cluster plots are dispersed. 6) In the Off-Target Variant (OTV) class, the cluster plot displays a fourth, vertically displaced cluster that precludes confident genotype calling. In addition, a seventh group of genotyping results for mSNPs (designed to reduce complexity in the octoploid germplasm) were provided but these were not classified, and these are grouped as Not Classified (NOCLS).

Pedigree based marker-trait analysis

In order to be used for pedigree analysis, the SNPs had to be qualified as concordant in the pedigree for each family and generation using the same methodology as used in Chapter I for the mapping population and founding parents. The pedigree with flower color information was displayed using Pedimap (Voorrips et al. 2012). The genotypic calls of the NW and W progeny were compared to each other and to the three founders, FC1, FC2 and FC3 to identify an association between the NW phenotype and genotype. A marker-trait association was identified as a consistent pattern of alternate genotypes of W colored flowers from the genotypes of NW flowers across the four generations. Specifically to be considered a marker-trait association, the genotyping pattern would be as follows: 1) both W founders (FC1 and FC3) and all of the W progeny would have the same genotype; 2) the NW founder (FC2) and all of the NW progeny would have the same genotype; and 3) the NW and W would not have the same genotype.

Comparison to FvH4

The sequences of genes identified as related to the anthocyanin pathway were obtained from various sources as cited in the introduction. Using the deposited sequence accession identification number, the sequence fasta file was obtained from either NCBI blastx (Altschul et al. 1997) at http://www.ncbi.nlm.nih.gov or EMBL_EBI at http://www.ebi.ac.uk. The sequences were then subjected to Blastn searches on GDR NCBI blast (Jung et al. 2013) at http://www.rosaceae.org to obtain the location on FvH4 v1.1. The GeneMark ID was obtained on GBrowse (Jung et al. 2013) by zooming on the FvH4 v1.1 PC and base-pair location.

Results

Population development

Population development through crossing and selections was partitioned into two distinct phases. Phase 1 has generated over 1000 progeny plants from crosses involving wild germplasm and one cultivated variety, FC2, which was the source of the NW trait. Within Phase 1, the 455member Closed Pedigree Set, was derived exclusively from FC1, FC2, and FC3 (Figure 2.2). The Closed Pedigree Set included the 41 members of the 'Select Set' chosen for genotyping on the Array. Phase 2 involved crosses between selected individuals from Phase 1 and some commercial cultivars.

Figure 2.2: Founders of the Closed Pedigree Set. The photos display typical flowers and fruit from each of the three founders: FC1, FC2, and FC3.

Phase 1 – The Closed Pedigree Set (Figure 2.3) encompassed four generations and 18 progeny families. The Closed Pedigree Set is segregating for numerous traits in addition to NW versus W flower color, and include floral hue, sex (female versus hermaphrodite), flowering habit (day-neutral versus short day), and aspects of fruit quality. The families of the Closed Pedigree Set averaged N = 25 in size, with a range of N = 6 to 100 (Table 2.2 and Figure 2.3). Overall, the percentage of NW members increased with each generation, ranging from 13 to 17% in the second generation and from 56 to 100% in the fourth generation. In NW \times W crosses, the percentage of NW progeny ranged from 13 to 17% in the second generation, and from 42 to 100% in the fourth generation. In NW \times NW crosses, the percentage of NW progeny ranged from 71 to 72% in the third generation, and from 56% to 100% in the fourth generation. Crosses between two W members resulted in only W progeny. In some progeny families, and particularly in the self of LMJ6, some members have never been observed to flower, and therefore their floral characteristics are unknown. The families also segregated for a rainbow of hues starting in the second generation, with the first incidence of red flower color occurring in the third generation.

<u>Phase 2</u> – In Phase 2, selected members of Phase 1 families were crossed with various cultivars, and among the progeny were hybrids with desirable flower hues and fruit quality. So far, particular attention has been given to one promising Phase 2 family. The LM49 family (N=93) derived from Cavendish \times LMJ6 (third generation selection from Closed Pedigree Set) had 47% NW progeny. This family is typified by a broad range of flower hues and attractive and flavorful fruit. Members of the LM49 family have been selected by Pleasant View Gardens for evaluation. Phase 2 is ongoing, and its full description goes beyond the scope of this thesis.

Table 2.2: Phase 1 segregation for flower color and hue. The columns (left to right) report generation (Gen) number, the family name (Name), the counts of members with the flower hues according to the color code below, NW versus W versus unknown (Unk) flower color, and the family size (FamSize) are provided. The hues are as follows:

■ Whte ■ Scrlt ■ SIPk ■ DSIPk ■ Red ■ Pk ■ LPk ■ Dpk ■ Fush ■ Lav ■ LCor ■ Cor ■ Unk

Figure 2.3: Flower colors in the four generation Closed Pedigree Set. The pie-charts represent the distribution of W and NW members by hue within families, by generation (left to right). N = number of individuals per family. The female parent is connected to its progeny with a red line, while the male parent is connected with a blue line.

The Closed Pedigree Set provides a diverse germplasm resource for advancement of marker-assisted strawberry breeding, and is being used in Phase 2 of my program to develop hybrids with desirable flower colors, flowering habits, and favorable fruit shape, size and quality.

Figure 2.4: Fruit quality improvements under selection. These photos display visually proportional variation in fruit shape and size. The sizes are according to the displayed scale in cm. The fruit size in the first three generations of Phase 1 was very small, while in the fourth generation there were instances of attractive and reasonably good-sized fruit. At the lower right, a fruit from a selected, red-flowered LM49 (Phase 2) family member is shown, depicting the gain in fruit size in combination with desirable flower hue.

Phenotyping – Flower color and pigment composition

<u>Presence/absence of flower color</u> – In general, flowering plants displayed either NW or W flower color (as in Figure 2.2) and could be unambiguously categorized as such. However, there were also numerous examples of irregular flower color patterns on plants with otherwise uniformly pigmented flower petals, including bicolored petals and flowers (Figure 2.5). The occurrence of 'twin spots', which consist of paired white and highly pigmented streaks and spots (panel c of Figure 2.5) is particularly noteworthy as will be discussed later. In one instance half of a flower was white with yellow anthers, and other half was red with red anthers (panel h of Figure 2.5).

<u>The hues of NW flowers</u> – NW flower hue displayed a pattern of continuous (i.e., quantitative) variation in the Closed Pedigree Set. The NW flowers (Figure 2.6) had variant shades of color, and variable color patterns such as darker rays, venations (panel h of Figure 2.6) or margins (panel b of Figure 2.6). The colors and color patterns of anthers were also variable among plants (Figure 2.6). Flowers of some plants have vestigial anthers or lack anthers entirely, thereby influencing the overall appearance and color pattern of the flower (Figure 2.6).

Cyanidin and pelargonidin contents of flowers – Floral cyanidin and pelargonidin contents were determined in 31 NW plants of the Closed Pedigree Set, including 27 from the Select Set. Four of the NW Select Set members were not flowering during the course of pigment analysis and could not be assayed. For comparison, one W-flowered member of the Select Set was also assayed. Flower petals that were entirely white had no detectable cyanidin or pelargonidin.

Figure 2.5: Sampling of flowers with unusual color patterns. These flowers were on plants with otherwise uniformly pigmented NW flowers. The flower shown in panel i was part of an inflorescence upon which all flowers had pink axial rays, while the rest of the plant had red flowers. In panel c, the flower has an apparent "twin spot" phenotype. Other flowers display various mosaic forms.

Figure 2.6: A sampling of the hues of NW flowers. The flower pictures display a sampling of the diversity of flower hues in Phase 1 and Phase 2 members. The pictures also show a diversity of anther presence/absence, and anther colors and color patterns. LM12-35, the member with the highest floral content of cyanidin and pelargonidin is shown in the bottom photo. The white mesh bags are enclosing a flower bud which has been emasculated and pollinated.

The variation in cyanidin and pelargonidin contents for the NW flowers Closed Pedigree Set is shown in Table 2.3 and Figure 2.7. The NW flowers varied over a wide range of anthocyanidin contents161 to 4256 μ g/g: including 88 to2419 μ g/g cyanidin and 15 to 1837 μ g/g pelargonidin contents (Table 2.3 and Figure 2.7). FC2 had intermediate contents of cyanidin and pelargonidin, 1,200 and 170 μ g/g, respectively, for a total of 1370 μ g/g anthocyanin. Most notably, fourth generation selection, LM12-35, with deep red flower petals (Figure 2.6 bottom photo and panel g), had exceptionally high cyanidin and pelargonidin contents of 2,419 and 1837 μ g/g, respectively. Conversely, LM69-3 pink flower petals (Figure 2.6 panel f) had the lowest cyanidin and pelargonidin contents of 146 and 15 μ g/g, respectively.

Among assayed NW flowers in Phase II individuals of the LM49 family, cyanidin and pelargonidin contents ranged from 165 to $669\mu g/g$ and 41 to $640\mu g/g$, respectively. For comparison, one W-flowered member of the LM48 family was also assayed. Flower petals that were entirely white had no detectable cyanidin or pelargonidin. Plant number LM49-64 stood out as having a a particularly high floral cyanidin content of 669 $\mu g/g$ (Figure 2.8).

Phenotyping – Fruit color and pigment composition

Fruit pigmentation could not be assayed in the Select Set or other Closed Pedigree Set members due to poor and irregular fruit set. There was however visible evidence of variation in fruit hue and some fruit were very light, but not W. In the Phase 2 LM49 family, fruit cyanidin and pelargonidin contents were 56 to 163 and 159 to 1178 μ g/g, respectively (Table 2.4). Plant number LM49-64 stood out as having particularly high fruit pelargonidin content (Figure 2.8). The previously tested cultivars had fruit cyanidin contents ranging from 27 to 120 μ g/g, while their pelargonidin contents ranged from 402 to 761 μ g/g (Table 2.5).

<u>Phenotyping – Additional traits</u>

<u>Fruit size</u> - Fruit size was variable within families, and increased under selection from the second through the fourth generation of Phase 1 (Figure 2.4). Thus far, the largest fruit have been found in members of the LM18 family, while one member of the LM9 family (LM9-6) produced the most fruit and the most attractive fruit over the longest duration (fourth generation larger panel in Figure 2.4). In Phase 2 of my program, hybrids with desirable fruit shape, size and quality are being developed, with initial focus on the LM49 family (Phase 2 panel in Figure 2.4).

<u>Other traits</u> - Sex expression (female versus hermaphrodite) segregated in some progeny families, while in others only hermaphrodites were seen. The seasonal flowering pattern varies: starting early (mid-April to mid-May) to late (late-June), with or without repeated flowering. In addition, there is variability among the progeny for presence/absence of flowering on the runners, an important trait for ornamental potted plants.

Table 2.3: Flower petal cyanidin and pelargonidin contents for Closed Pedigree Set listed by generation. Key to column headings: Cyn = cyanidin; Plr = pelargonidin; Anth = total anthocyanins.

Figure 2.8: Flower and fruit anthocyanidin (cyanidin and pelargonidin) contents in representative members of Phase 2 LM49 family. The two shaded ovals outline anthocyanidin ranges for flowers (red diamonds) and fruit (orange squares). Arrows indicate the extreme positions of plant LM49-64 with respect to flower cyanidin and fruit pelargonidin contents.

Genotyping

SNP Array genotyping results obtained for 51 individuals included the following: a Select Set of 41 plants comprised of the one NW- and two W- flowered parents and 31 NW- and 8 W-flowered progeny individuals (Table 2.6 and Figure 2.9); and a diverse sampling of 10 other W-flowered "non-ananassa" germplasm accessions representing *F. virginiana* and *F. chiloensis* and a few hybrids thereof.

Segregating markers in the Select Set - A total of 5,674 parentally concordant, segregating markers were identified in the Select Set. These 5,674 concordant markers constitute 6.2% of the 95,062 marker sites on the Array, and include all of the recognized marker categories (Table 2.7). The octoploid-based SNPs had a higher success rate (6.5%) compared to the diploid-based (1.3%) and codon-based (1.1%) SNP groups (Table 2.7). The markers were fairly well distributed in relation to the seven pseudochromosomes (PCs) of the *F. vesca* FvH4 reference genome as indicated by the distribution of markers on the array, and the success rate ranged from a low of 4.7% for PC7 to high of 7.4% for PC1 (Table 2.8).

Table 2.6: Pedigree of Select Set. The members are identified by generation, name, female and male parentage, flower color category (NW versus W), and flower hue, where Petal1 indicates the overall hue of the petals, and Petal2 indicates a second tone in the flower petal, usually at the central axis. The abbreviations for the hue categories are provided to the right of the table.

Total	95,062	5,674	6.0%

Pedigree based marker-trait analysis

In a marker-trait analysis of NW versus W flower color in the Select Set pedigree using 5,674 concordant Array markers, initially only 5 markers displayed an absolute association with NW flower color. However, among the 41 members of the Select Set, the phenotype and genotype of one individual, LM69-4, was in question, and required closer consideration. A review of photos of LM69-4 showed that the plant generally produced dark pink flowers, but on at least one occasion produced an inflorescence with lighter salmon pink flowers and on another occasion produced a dark pink flower with one white petal with red rays or venation (Figure 2.10). In addition, in the SNP genotyping data set, LM69-4 had a borderline QC quality of 96% compared to the general cutoff of 97%, as recommended by Affymetrix. Examination of the cluster plots of the initially identified five markers showed that the LM69-4 cluster diagram sample "dots" were generally falling outside the range of what is considered good quality genotyping calls (Figure 2.11). LM69-4 was thus excluded from further consideration in the marker trait analysis, based on the observed seemingly unstable phenotype for the color trait and the low quality genotyping calls.

The exclusion of LM69-4 resulted in identifying an additional 30 markers that were cosegregating without recombination with the NW trait, for a total of 35 trait-associated markers (Table 2.9). Overall, at these 35 marker sites, the NW founder, FC2, and the 30 NW progeny possessed the NW-associated allele and genotyped as heterozygous (Table 2.9), while the W founders FC1 and FC3 and all W progeny lacked the NW-associated allele, and genotyped as homozygous for an allele that did not come from FC2. These 35 markers included 30 octoploidbased (28 Snps, two mSnps), two diploid-based and three codon-based SNPs. An additional 14 markers numbered 36 through 49 in Table 2.9 were identified as loosely associated but with some recombination to the NW trait.

Figure 2.10: LM69-4 variable phenotypes. The larger picture shows two inflorescences, each with a different hue on the same plant; an inflorescence with the typical dark pink flower color of LM69-4 (left) and an inflorescence that is a lighter coral color (right). The inset picture on the lower left shows two single flowers taken from LM69-4: one flower with a single white petal with dark pink rays or venation, and the other flower with the typical LM69-4 dark pink.

Figure 2.11: Typical Array cluster plots for markers associated with the NW flower color trait. For each of three markers from Table 2.6, the plots include the genotyping of the Select Set of 41 and 10 W "non-ananassa" genotypes. The arrows point to corresponding genotype/phenotype colored according to the Color Code legend. The lower intensity (quality) of LM69-4 can be seen by the lower displacement of the respective dots in the plots for markers 2 and 3. The least frequent allele considered the minor allele. The shift of the plots away from 0 on the x-axis is indicative of the background allele copy number, such that the genotype for an octoploid is shifted away from the 0 on the x-axis. The plots are shifted relative to the x-axis as influenced by the underlying octoploid genotype; marker 1 is shifted to the positive indicating an 'A' background allele, marker 2 to the negative indicating a 'B' background allele. For example, marker 1 is shifted to the positive and therefore has the genotype BA AA AA AA which corresponds to CT TT TT (Table 2.9), with 'C' minor allele and the marker allele being one and the same. Marker 2 is shifted to the negative, and therefore has the genotype AB BB BB BB, which corresponds to TC CC CC CC, with 'T' minor allele again being one and the same as the marker allele (Table 2.9).

Table 2.9: Marker-trait associations. Thirty-five markers (numbered #1-35 in column 1) are linked without recombination to the NW color trait. Only markers #4, 14, 15, 21, 28, and 32 were associated with NW color before exclusion of LM69-4. Markers #36-49 are associated but with some recombination with the NW trait. The marker allele associated with NW is highlighted dark green (Allele 0 and Allele 2 columns).

Comparison to F. vesca FvH4

The marker-trait associations for NW flower color include 35 markers that are associated without recombination. Of these 35 markers, 28 are syntenous with PC5 of the *F. vesca* FvH4 reference genome (Table 2.9), and their positions span the entire chromosome (Figure 2.12). A single associated marker, #32 AX-89828940, is syntenous with PC4, but appears to be mislocated in the FvH4 genome because it is clearly positioned within a block of 39 contiguous markers on LG5 of the *F. iinumae* map (Table 2.9, Figure 2.12, and Chapter I). Of the remaining 6 markers, three (#1, 2, and 3 in Table 2.9) are syntenous with PC1 and three with PC6 in FvH4. These three markers with synteny to PC1 are positioned among six other markers that are proximally located in FvH4 PC1 and are also mapped to LG1 of the *F. iinumae* map (Chapter I). The three markers (#33, 34 and 35 Table 2.9) with synteny to PC6 are scattered in PC6, and their locations could not be assigned on the *F. iinumae* map.

On the basis of a homology search, 19 genes related to the anthocyanin pathway were located on various PCs of the FvH4 reference genome (Table 2.10). Six of these genes are located within the color-trait association, and all six of these genes are located on PC5 of FvH4, and are therefore of the greatest interest as candidate genes with respect to the NW trait. The six genes include four structural genes, *ANR*, *ANS*, *F3'H*, and a *Ph* gene; and two regulatory genes *JAF13* and *FaMYB1* (Table 2.10).

Table 2.10: Location of identified anthocyanin related structural and regulatory genes on FvH4 PCs. The GeneMark ID for the genes that were annotated is provided. No GeneMark IDs are available for PC0, which consists of unplaced scaffolds and therefore has not been annotated. The start and end position of the annotated genes are indicated in base-pairs (bps).

Figure 2.12: Markers associated with color and anthocyanin related genes on *F. iinumae* **21F2D LG5 and** *F. vesca* **FvH4 PC5.** One marker located FvH4 PC4 (left diagram) linked to flower color is located on LG5 of the 21F2D map. Thirty of the 35 markers are syntenous with FvH4 PC5. The locations of five anthocyanin related genes are indicated on PC5 (right).

120

Discussion

The population development effort began with the initial cross made in 2007, and has resulted in the establishment of over one thousand progeny, thereby leading to the advancement of breeding objectives for flower color and fruit quality. The primary focus of phenotyping has been flower color and hues, as determined visually and complemented by HPLC analysis of pigment composition to the extent possible. Fruit quality was also of central interest. The numbers of plants subjected to both SNP Array genotyping and HPLC analysis of flower and fruit pigment contents is as yet comparatively small. The populations and results described here provide a foundation for a marker-assisted strawberry breeding program emphasizing the integration of ornamental value and fruit quality for specialty markets. The Select Set of 41 individuals has provided the basis for identifying marker-trait associations and identifying candidate genes for potential identity with the locus governing NW versus W flower color.

Genetic basis of the NW trait

In the Closed Pedigree Set, the outcomes of NW \times NW, NW \times W and its reciprocal (W \times NW), and W \times W crosses provide the basis for inferring that the presence of non-white (NW) flower color is genetically dominant to its absence, white (W) flower color. This conclusion is supported by the fact that W \times W crosses gave only white progeny, while 7 out 8 NW \times NW crosses generated segregating progenies. In the exceptional case, all members of the small (N = 11) LM69 family were NW, perhaps by chance alone. The fact that segregation occurred in the

second generation LMA and LMB families indicates that FC2, the original source of the NW flower color trait, was itself heterozygous. Moreover, the presence of segregation in all but one progeny family involving at least one NW parent suggests that homozygosity for the NW trait was rare or absent in the NW members of the Closed Pedigree Set. If so, an explanation for such genotypic bias will be sought through future investigations.

<u>Presence/absence of flower color</u> - The occasional presence of mosaic flowers of plants with NW flowers (Figure 2.5 panels a through h) suggests that the presence of color is conferred by a single gene copy, the loss or inactivation of which results in a white sector. This hypothesis is consistent with the widespread heterozygosity for the NW trait as noted above. On this basis, doubling of the gene copy number, perhaps by a somatic recombination event, could produce a very dark sector, as seen in Figure 2.5, panels a and c. The increasing frequency of NW individuals in the advancing generations of the Closed Pedigree Set is likely the result of the imposed selection for NW flower color, in combination with repeated opportunities for genetic recombination in the advancement of one generation to the next.

Variation in floral hue

In addition to the presence/absence of color, a broad spectrum of floral variations in hue, color intensity, and color pattern was evident (Figure 2.6), offering immense scope for selection of ornamental types. Figure 2.6 (panels a, c, g, and i) displays examples of red flowered selections, but with subtle differences in petal color intensity and hue accompanied in some cases by distinct differences in stamen color (compare panels a and c to panels g and i). There appears to be an association between petal hue and anther hue, as in Figure 2.6 (panels a, b, c, g, and i) where the darker colored flowers have reddish to red anthers, while the more pastel-shaded

flowers have yellow anthers (panels d, f, and h). Figure 2.6 panel c displays a strikingly attractive flower with deep red petals and stamens to match. Floral patterns with darker edges on the flower petals (Figure 2.6, panel b) look as though the petals had been outlined or painted with a darker shade of the same color, while in contrast, panel h shows a flower with dark axial rays that transition gradually to a lighter shade of the same hue toward the petal edges. The variation of hues and floral patterns among progeny family members is indicative of segregation at multiple loci, presenting a challenge to genetic analysis.

Cyanidin and pelargonidin contents of flowers - The fact that the NW founder parent FC2 had intermediate levels of cyanidin and low levels of pelargonidin contents suggests that the white-flowered parental founders, FC1 and FC3, may be contributing hereditary factors influencing floral hue in the subsequent progeny generations, including the appearance of red flower color in the third and fourth generation of the Closed Pedigree Set. The ranges of cyanidin and pelargonidin in the flowers of the Phase 2 LM49 family were much lower than those of the Phase 1 Closed Pedigree Set (Figure 2.13), as might be expected because the LM49 family samples the alleles of only one Select Set member, LMJ6, which has an intermediate level of floral pigments. In the LM49 family, which was derived from a W cultivar Cavendish x NW LMJ6, some progeny members had floral cyanidin contents as much as twice that of their NW parent LMJ6, yet progeny pelargonidin levels were much less than or equal to that of the NW parent, suggestive of contributory hereditary factors from 'Cavendish' for cyanidin but not for pelargonidin in this family.

Figure 2.14: Cyanidin and pelargonidin contents in fruit. The anthocyanin content of fruit of members of Phase 2 (LM49 family) and an assortment of cultivars tested previously (Mahoney 2007).

125

Comparison of flower and fruit pigment contents

Fruit set was generally not abundant or consistent in Phase 1, precluding the generation of useful data on fruit pigment composition. In contrast, improved fruit production and quality in the Phase 2 LM49 family enabled acquisition of fruit (Figure 2.14) as well as flower pigment composition data, permitting useful comparisons between flower and fruit pigment composition in that family. The ranges in cyanidin and pelargonidin contents in a sampling NW flowers and fruit from members of the LM49 population contrasted with each other in interesting ways (Figure 2.8, Table 2.4). Plant LM49-64 was an outlier, having exceptionally high floral cyanidin and fruit pelargonidin (Table 2.5). Excluding this exceptional plant, the range of cyanidin contents was higher and broader in NW flowers than in fruit (Figure 2.8, Table 2.4). Contrastingly, the range of pelargonidin contents was similar in both NW flowers and fruit, again with the exception of plant LM49-64 (Figure 2.8). The comparison of flower and fruit pigment compositions suggests an elevation of cyanidin biosynthesis in flowers as compared to fruit, while no such elevation is seen with pelargonidin. Interestingly, the ranges of cyanidin and pelargonidin contents in the fruit of the LM49 family (Table 2.4) are comparable to those of commercial cultivars previously assayed (Mahoney 2007) (Table 2.5, Figure 2.14).

The LM49 NW progeny display a palette of floral hues, suggesting that one or both parents must be heterozygous for loci influencing floral hue, providing opportunity for recombination in future generations. The very good fruit quality in some of the members is indicative of inheritance from Cavendish, but also of complementation with LMJ6, as the fruit did not resemble that of either parent. Moreover, the interest of Pleasant View Gardens in evaluating ten members of this family as ornamental selections and in continuing our relationship towards further varietal improvement justifies continued intensive breeding efforts involving the LM49 family.

Phenotyping - Additional traits

The Select Set is also segregating for other traits, including flowering habit (dayneutrality versus short-day), and fruit size and shape. It is reasonable to expect that these populations are also segregating for other fruit quality traits of interest, such as fruit pH, titratable acid, and soluble solids. In the Phase 2 LM49 family, the fruit size (8-12 g/berry) was comparable to that of cultivars, ranging from 7.2 to 15.5 g/berry (Gent 1990), and similar to that obtained at UNH of 4.2 to 11.2 g/berry for an assortment of cultivars during the RosBREED phenotyping project (Mathey et al. 2013).

Genotyping

The number of concordant markers (5,674) in the Select Set is comparable to the 6,594 concordant markers mapped in the *F*. ×*ananassa* Holiday × Korona cultivar cross, of which 80 progeny members and the parents were also genotyped on the evaluation phase of the Array (Bassil et al. manuscript submitted). The sequence files of 'Holiday' and 'Korona' and six of their progeny were a major part of the discovery panel used in the design of the Array. Although the founders of the Closed Pedigree Set were part of the discovery panel, the low depth of coverage on the sequence data precluded them as major contributors to the design. The final result however indicates that there contribution to the design may have been a factor in the identification of a significant number of markers in the Select Set.

Marker trait association for flower color

The 28 markers associated with NW flower color are distributed over the entire length of reference chromosome PC5. This finding suggests that a chromosome derived from FC2 and containing the flower color locus is being transmitted in the Select Set without recombination. Presumably the NW flower color locus is located somewhere on this chromosome, in close proximity to a particular marker or markers. However, the absence of detected recombination in the limited number of 38 Select Set progeny individuals (Table 2.9) precludes the determination of more narrowly defined marker-trait associations, and also precludes the establishment of linear marker order except as defined by the marker locations on PC5 of the diploid reference genome.

In prior studies conducted by two research groups, quantitative trait loci (QTLs) for fruit quality have been identified on one of the LG5 homoeologues of *F.* ×*ananassa* ((Zorrilla-Fontanesi et al. 2011, Lerceteau-Kohler et al. 2012). Zorrilla-Fontanesi et al. (2011) found QTLs on a homoeologue of LG5 for each of the following traits; total anthocyanin, pH, titratable acidity, and color values (a*, b*, and C*) and markers for candidate genes co-localized with some of these QTLs. In another QTL study (Lerceteau-Kohler et al. 2012) of 19 strawberry fruit quality traits, 115 QTLs were detected; 4 QTLs for acidity traits and one for the color value a* were located on one of the homoeologues of LG5. However, QTLs for anthocyanin contents and fruit color (L a* b*) variation and additional QTLs for fruit acidity traits, were also found on linkage groups other than LG5 (Lerceteau-Kohler et al. 2012).

Candidate genes for flower color

The marker-trait association for NW versus W flower color involving 28 markers on PC5 suggests that the gene(s) conferring functional capacity for anthocyanin production in the flower is located on a homoeologue of chromosome 5, and that this chromosome was derived from the original source of NW flower color, founding parent FC2. Therefore, genes with potential influence on pigmentation characteristics and also located on chromosome 5 of the FvH4 reference genome are candidates for potential identity to the "NW locus". As identified by literature and homology searches, the identified candidate genes centered on PC5 include four structural genes, *ANR*, *ANS*, *F3'H*, and a *Ph* gene, and two regulatory genes, *JAF13* and *FaMYB1* (Table 2.10 and Figure 2.14). Candidate gene products influencing NW versus W might compete for the same substrate, and/or an enzyme might have tissue specific functionality or an enzyme might be non-functional. The likelihood of such enzymes influencing color is briefly discussed below within the context of the literature.

<u>ANR</u> - ANR activity was found to be three times higher on cyanidin as a substrate than on pelargonidin in strawberry, producing many times more epicatechin (from cyanidin) compared to epiafzelechin (from pelargonidin) (Almeida et al. 2007) (Figure 2.1). These findings suggest that *ANR* variants could influence hue but not NW versus W color in flowers and/or fruit.

<u>ANS</u> - ANS is at the point of conversion from colorless to colored compounds in the anthocyanin biosynthetic pathway (Figure 2.1) (Holton et al. 1995). It is conceivable that the *ANS* gene is duplicated and sub-functionalized into fruit-specific and flower-specific forms in strawberry. Loss of flower but not fruit pigmentation could result from a mutation in the floral-specific gene copy. A functional gene copy of *ANS* may exist in FC2. On this basis, *ANS* is a viable candidate gene.

<u>F3'H</u> – F3'H can catalyze the conversion of eriodictyol and dihydroquercetin precursors to cyanidin (Figure 2.1). A mutant line of petunia transformed with an overexpressed F3'H had pink flowers with pink anthers and pollen containing peonidin (an anthocyanin derived from a cyanidin), compared to pale lilac control which contained very little anthocyanin (Brugliera et al. 1999). Only the hue of the transgenic petunia flower was affected, but not whether the flower was NW or W. Thus, these finding do not support F3'H as a candidate gene for the NW flower trait.

<u>*Ph* gene</u> - Griesbach (1996) found in *Petunia* ×*hybrida* that vacuolar pH affected flower hue and not the presence or absence of color and thus the *Ph* gene is not a likely candidate gene for the NW flower trait.

<u>JAF13 and FaMYB1</u> - The c and r family of genes control the transcription of all the structural genes of the anthocyanin pathway (Quattricchio et al. 1998). The c family encodes MYB transcription factors. *JAF13*, by NCBI blast homology to *Arabidopsis thaliana* (gb|AAB72192.1|), is part of the r gene family, the members of which encode basic helix-loophelix (bHLH) regulatory proteins. The bHLH transcription factors alone or in combination with MYB factors have been found to control presence versus absence of anthocyanin pigmentation in flowers (Quattricchio et al. 1998).

Expression of *FaMYB1* in *F.* ×*ananassa* 'Elsanta' strawberry was found to be the highest in ripe red fruit and to be low in the flowers (Aharoni et al. 2001). Tobacco was used as a model system for ascertaining the function of FaMYB1 (Aharoni et al. 2001). Heterologous expression of *FaMYB1* in tobacco reduced anthocyanin and quercetin (a flavonol) levels. The overexpression of FaMYB1 in tobacco was found to be inversely correlated with the synthesis of anthocyanin pigments in the tobacco flowers (Aharoni et al. 2001). Overexpression of FaMYB1 in tobacco resulted in flowers ranging from white, white with red venations, to slightly colored, in comparison to the dark pink flowers of the wild type (Aharoni et al. 2001), suggesting that FaMYB1 acts as a repressor of the anthocyanin expression in flower. The flower in panel i of Figure 2.5 is nearly identical to that shown by (Aharoni et al. 2001) for transgenic overexpression of FaMYB1 in tobacco by introduction of 3-4 copies of the transgene in the plant resulted in a white flower.

In a comparison of co-constructs using a yeast two hybrid system, Aharoni et al. (2001) determined that *FaMYB1* and *AN2* do not contain an active *bHLH* binding domain, in contrast to AN1 and JAF13 which do contain an active bHLH binding domain. The lack of an active bHLH binding domain on *FaMYB1* may imply that the regulation of the anthocyanin pathway genes is in conjunction with JAF13. In FaMYB1 transgenic tobacco, the active bHLH may have been present, allowing repression of the anthocyanin pathway and resulting in white flowers. Therefore, are strawberry flowers white because FaMYB1 works together with JAF13 to repress the anthocyanin pathway in strawberry flowers, so that a non-functional MYB1 or a nonfunctional JAF13 would enable NW flower color? With the introgression of NW flower color trait from FC2, the capacity for NW was introduced into the strawberry flowers. Unlike tobacco with normally pink flowers, the overexpressed FaMYB1in transgenic tobacco displayed white flowers, implying that tobacco already contained an active bHLH domain. Has a non-functional type of MYB1 or a non-functional bHLH transcription factor similar to AN2 been introgressed in the NW strawberry from FC2, thereby preventing the full expression of FaMYB1 and the concomitant repression of the anthocyanidin pathway genes such as ANS and F3'H, resulting in NW flowers? Exploration of these hypotheses will require gene expression analysis, and could be an attractive objective for future research.

In conclusion, the most likely candidate genes influencing NW versus W trait are the two regulatory genes *FaMYB1* and *JAF13*, and the structural gene *ANS*, while the remaining structural genes, *ANR*, *F3'H*, and a *Ph* gene are better suited as candidate genes for influencing quantitative variation in floral hue.

The identification of a marker-trait association for NW flower color in this analysis with only 38 progeny members offers promise for discovery of additional trait associations with the anticipated analysis of genotypic data for additional members of the Closed Pedigree Set. The anticipated analyses may elucidate the identity of the locus conferring NW flower color, as well as loci conferring variation for flower hues.

At this writing, I am anticipating Array genotyping data for an additional 104 members of the Closed Pedigree Set, which will provide a sufficient population to construct a linkage map of LMJ6, a third generation red-flowered member that has all three founders in its heritage, and to complete quantitative trait loci analyses for NW flower trait and fruit quality traits.

CHAPTER III

GERMPLASM RESOURCES FOR VERTICILLIUM WILT RESISTANCE BREEDING AND GENETICS IN STRAWBERRY (*FRAGARIA*)¹

Abstract

We screened 26 octoploid, 1 decaploid, and 23 diploid Fragaria (strawberry) genotypes for response to root-dip inoculation with Verticillium dahliae isolate V1. Inoculated plants were individually rated at eight weeks post-inoculation in comparison to uninoculated controls using a categorical scale: 1 = healthy; 1.5 = slightly symptomatic; 2 = moderately symptomatic; 2.5 = very symptomatic; 3 = dead. Qualitative classifications were assigned to genotypes on the basis of their respective mean disease resistance ratings. The rating ranges and corresponding classifications (in parentheses) were: 1.0 to 1.3 (very resistant = VR), 1.4 to 1.7 (moderately resistant = MR), 1.8 to 2.2 (intermediate = I), 2.3 to 2.6 (moderately susceptible = MS), and 2.7 to 3.0 (very susceptible = VS). Considerable variability in inoculation response existed within and between species at both the diploid and octoploid levels. VR or MR genotypes were found within each of the following species: diploids F. vesca, F. iinumae, and F. *nipponica*); and octoploids F. *chiloensis*, F. *virginiana*, and F. *×ananassa*. MS and VS genotypes were

¹ This chapter is revised from a manuscript is submission process to Genetic Resources and Crop Improvements Vining, K.J., T.M. Davis, A.R. Jamieson, L.L. Mahoney. **Verticillium** wilt resistance varies within ploidy levels in strawberry (*Fragaria* spp.)

documented within *F. vesca*, within each octoploid species, and in a genotype of decaploid *F. cascadensis*.

We then compared our screening results to those of previous studies, aided by a constructed pedigree of evaluated and related octoploid cultigens (cultivars and breeding clones). We also made resistant \times susceptible crosses at both the diploid and octoploid levels as a step toward genetic analysis of wilt resistance/susceptibility and resistance gene identification in strawberry.

Introduction

The fungal disease verticillium wilt has been a major obstacle to U.S. strawberry production since first identified and described by Thomas (1931). In most major U.S. strawberry production areas, methyl bromide and chloropicrin have been the foundation for control of soil-borne disease organisms (Samtani et al. 2012), including *Verticillium dahliae* Kleb., the causal agent of verticillium wilt. However, the classification of methyl bromide as an ozone depleting chemical under the Montreal Protocol in 1987, and by the U.S. Environmental Protection Agency in 1993, has prompted the development of alternative chemical treatment practices (Environmental_Protection_Agency 2013). Non-chemical alternatives such as steam and solarization treatments have shown promise, but have not been demonstrated to be cost effective (Samtani et al. 2012). Verticillium wilt was a serious disease before the advent of soil fumigation (Shaw et al. 1997, Sjulin 2003), and it continues to be a significant problem for strawberries.

At least partial relief from the problems posed by verticillium wilt could be provided by incorporation of genetic resistance into new commercial strawberry varieties. While enhanced wilt resistance has been obtained in strawberry via the introduction of a chitinase gene (Chalavi et al. 2003), the genetic engineering approach would also negate the opportunity to exploit the burgeoning organic production niche. The skyrocketing demand for organic strawberries from \$2 million in 1997 to \$55 million in 2009 has stimulated intensive interest among breeders in the prospect of developing wilt resistant strawberry varieties (Koike et al. 2012). The foregoing realities emphasize the need to identify and exploit naturally occurring sources of genetic resistance and the need to breed for resistance.

Quantitative genetic variation for field resistance to verticillium wilt was documented in cultivated strawberry breeding populations in the mid-twentieth century (Varney et al. 1959, Bringhurst et al. 1961, Bowen et al. 1968) and more recently by (Shaw et al. 1996), Shaw et al. (1997), (Shaw et al. 2003), indicating the potential for enhancing resistance through breeding. Shaw et al. (2005) asserted that genetic resistance to wilt is best regarded as one component of an integrated management system that also includes efforts to reduce pest populations at all growth stages. Nevertheless, it is evident that considerable potential exists for improving wilt resistance through germplasm evaluation and breeding, and that the full potential for genetic resistance to verticillium wilt in the cultivated strawberry has yet to be defined or realized.

The strawberry genus *Fragaria* is remarkably diverse, encompassing more than 23 species and spanning ploidy levels from diploid (2n = 2x = 14) to decaploid (2n = 10x = 70) (Staudt 2009, Nathewet et al. 2010). The octoploid (2n = 8x = 56) cultivated strawberry, *Fragaria* ×*ananassa*, is known to have arisen via hybridization between its octoploid ancestors, *F. chiloensis* and *F. virginiana*, in the mid-1700s (Darrow 1966). Phylogenetic and genomic studies have implicated ancestral forms of diploids *F. vesca* and *F. iinumae* as likely genome donors to the octoploid (Folta et al. 2006); however, the evolutionary pathway from the diploid to the octoploid level is yet to be delineated (Davis et al. 2009). Each of the ancestral octoploids has multiple subspecies: *F. chiloensis* has subspecies *chiloensis*, *patagonica*, *lucida*, and *pacifica*; while *F. virginiana* has subspecies *virginiana*, *grayana*, *glauca*, and *platypetala* (Staudt 1999).

An effort to reconstruct *Fragaria* \times *ananassa* by crossing representatives of *F. chiloensis* and *F. virginiana* was initiated (Hancock et al. 1993) and is ongoing (Hancock et al. 2010).

A broad sampling of the diversity present in *F. chiloens* is and *F. virginiana* is represented by the 38 accessions comprising the USDA "supercore" collection (Hancock et al. 2000). We have obtained this collection from the National Clonal Germplasm Repository (NCGR) in Corvallis Oregon, and maintain it as part of a broader collection of over 600 genetically unique strawberry plants, including species, hybrids, and segregating populations, at the University of New Hampshire. In the present study, we evaluated representatives of five diploid species, three octoploid species, and – serendipitously – one representative of decaploid *F. cascadensis*. At the time that this study was initiated, NCGR accession CFRA 110 was identified as octoploid *F. virginiana* ssp. *platypetala*. However, it has since been determined to be decaploid (Nathewet et al. 2010), and to belong to the newly defined decaploid species, *F. cascadensis* (Hummer 2012).

Our ongoing investigations are concerned with defining new sources of resistance in cultivated and wild strawberry germplasm, and with advancing genetic studies on the basis of resistance/susceptibility. This communication is conceptually divided into two components. First, we present the results of our own inoculation screens aimed at identifying new sources of resistance: at the octoploid level as resources for breeding, and at the diploid level to facilitate efforts to isolate and characterize resistance genes. Second, we submit a compendium of previous verticillium wilt studies in strawberry, both wild and cultivated e.g. (Varney et al. 1959, Varney et al. 1960, Bringhurst et al. 1961, vanAdrichem et al. 1962, Maas 1984, Maas et al. 1989, Hancock et al. 1991, Shaw et al. 1996, Olbricht et al. 2009). As a means of effectively positioning our study within this historical context, we have constructed an extensive pedigree depicting the ancestries of the tested cultivars, and wherever possible, including their previously reported verticillium wilt resistance ratings. Although differing rating terminologies have been employed by previous authors, we have integrated the findings of previous investigators with our own.

Materials and Methods

Plant and fungal materials

Information about the studied plant accessions, their geographic origins (wildcollected materials) or breeding program sources, and their identification numbers (local and/or Plant Introduction) is provided for diploids and polyploids, respectively, in Tables 1 and 2. Subspecies designations are not provided for California accessions of *F. vesca* due to uncertainty in differentiating the subspecies *Fragaria vesca* ssp. *bracteata* from *F. vesca* ssp. *californica* and their possible hybrids. Among diploid accessions (Table 3.1); CFRA364.002, CFRA333.001, and CFRA520.001 were obtained from the NCGR,

accessions from Hokkaido, Japan were collected by Thomas M. Davis and Kim Hummer (Hummer et al. 2006), and GS1J was collected by Gunter Staudt. All other UNHnumbered accessions were collected by Davis. The polyploid accessions of octoploids *Fragaria virginiana* and *F. chiloensis*, and decaploid *F. cascadensis* belonging to the *Fragaria* supercore collection were obtained from the NCGR. The studied *F. ×ananassa* accessions were of interest to our breeding programs. Plants of 'Sparkle' and 'Tristar' were purchased from Nourse Farms, Whately MA, while the other cultivars and breeding lines were provided by Andrew R. Jamieson. As distinct from wild germplasm, we refer collectively to advanced breeding selections and named cultivars as cultigens. *F. ×ananassa* cultivars 'Annapolis', 'Cavendish', 'Evangeline', 'Mira', 'Wendy' (aka 'AC Wendy'), and 'Laurel' (tested as K93-20), and numbered breeding clones K05-9 and M903 were developed at the Agri-Food Canada Kentville Research Station, Nova Scotia, Canada. Cultivar 'Sparkle' is a 1942 release from the New Jersey State University breeding program (Darrow 1966), and was included as an old time Northeastern favorite. 'Tristar' is a 1981 release from the USDA Beltsville program and was included as a day-neutral variety.

Screening methods

A series of trials was conducted in which from five to 20 genotypes were screened. In each trial, each genotype was represented by three-to-four inoculated and two uninoculated (control) plants. Pots containing inoculated or uninoculated plants were maintained within separate containment trays, and plants were randomly distributed within the trays. Some genotypes were included in multiple trials.

Verticillium dahliae isolate V1 was obtained from Mansun Kong at Driscoll Strawberry Associates, Watsonville, CA, USA, and was originally isolated from an infected strawberry plant (M. Kong, personal communication). Plants were maintained in the UNH MacFarlane Greenhouse facility in Pro-Mix MycorrhizaeTM (Premier Tech Horticulture LTD, Canada), and were propagated by rooting stolons that were still attached to mother plants to produce runner plantlets. Runner nodes were pinned onto the surface of Metro-mix 360 (HummertTM International, Missouri) medium in 4" standard round polypropylene pots (Dillen Products Company, Ltd., Middlefield, Ohio) using staples made from plastic-coated wire. Plantlets were allowed to root for two weeks prior to separation from the mother plant and inoculation. Ten plantlets were rooted from each mother plant, and eight were ultimately used in each trial (four inoculated plantlets and four uninoculated controls). Concurrent with plant propagation, fungal inoculum was cultured in an appropriate volume (~10 ml for each plant to be inoculated) of autoclaved $Difco^{TM}$ Czapek-Dox broth (BD Biosciences). The broth, contained in 1L flasks, was inoculated in a laminar flow hood with two to four ~1 cm² pieces of fungus-covered Czapek-Dox agar from fungal culture plates. The inoculated broth was then incubated for two weeks at room temperature on an orbital shaker at 200 RPM.

On the day of inoculation, the fungal culture was strained through two layers of cheesecloth and one layer of Miracloth (EMD Millipore, Billerica, Massachusetts), and then centrifuged at 10,000 x g for 5 min. The culture medium was decanted and the conidial pellet was resuspended in a volume of sterile distilled water equivalent to that of the decanted culture medium. Conidia were quantified using a hemacytometer (Bright Light Counting Chamber Improved Neubauer, Hausser Scientific, Horsham Pa), and the suspension was diluted, if necessary, with sterile distilled water to $\sim 2 \times 10^7$ conidia/ml. Immediately prior to root dipping, rooted plantlets were separated from mother plants and trimmed to remove runners. Soil was shaken from roots prior to dipping. Root dipping was performed in 50-ml polyvinyl chloride pipet basins (Fisher Scientific, Pittsburgh, PA). Root systems were immersed, two at a time per basin, for 5 min in either 20 ml fungal spore suspension or 20 ml sterile distilled water (uninoculated control). After dipping, the plants were replanted in new 4" pots containing sterile (autoclaved) Metromix medium, and then moved to a greenhouse under ambient light and temperature conditions or to a 22 °C temperature-controlled growth room under broad-spectrum (140 µmoles/m²/sec) fluorescent lights. Plants were then maintained in containment trays with minimal watering for a period of at least eight weeks.

Plant verticillium wilt disease rating

At the end of the observational period, each individual plant was rated relative to controls according to the following rating scale, as exemplified by plants shown in Figure 3.1. A rating of 1.0 (healthy) was given to plants closely resembling uninoculated controls. A rating of 1.5 (slightly symptomatic) indicated mild stunting and/or mild outer leaf necrosis and/or browning. A rating of 2.0 (mildly symptomatic) indicated distinct stunting and/or distorted growth, more leaf necrosis and browning, and perhaps one or two dead leaves. A rating of 2.5 (very symptomatic) was given to plants with severe stunting, leaf necrosis and browning, yet still having one to a few green leaves. A 3.0 (dead) rating indicated that all of the leaves were necrotic and the plant was considered to be nearly or completely dead. Each accession was initially represented in each trial by four inoculated plants, plus controls; however, in a few

Figure 3.1: Disease ratings and examples of their respective verticillium wilt phenotypes. Within each panel, a control plant is shown on the left, and an inoculated plant of the same variety is shown on the right along with its disease rating (number in black box).

cases, a plantlet was lost due to causes not related to verticillium wilt, and only three inoculated plants were rated. For each accession, the mean rating and associated standard deviation were calculated over the total number of replicates.

As guided by previous literature (Bringhurst et al. 1961, Bringhurst et al. 1966, Olbricht et al. 2009), we then assigned a classification to each genotype based upon its mean disease rating. The rating ranges and corresponding classifications (in parentheses) were: 1.0 to 1.3 (very resistant = VR), 1.4 to 1.7 (moderately resistant = MR), 1.8 to 2.2 (intermediate = I), 2.3 to 2.6 (moderately susceptible = MS), and 2.7 to 3.0 (very susceptible = VS).

<u>Summary of published sources of verticillium wilt resistance ratings in octoploid</u> <u>strawberry</u>

Relevant information sources were identified using searches of scientific literature and the USDA Germplasm Resources Information Network (GRIN) database (http://www.arsgrin.gov/), and keyword web searches. The pedigree relationships of the rated cultigens were then determined by extracting relevant information from the RosBREED "Breeding Information Management System" (BIMS) crop reference set for Fragaria (http://www.rosaceae.org/breeders_toolbox), and integrating it with information from published cultivar release announcements to create a project-specific database. Verticillium resistance ratings from the present study (Table 3.2) and resistance categories from various literature sources (Table 3.3) were then added to the database. We traced the pedigrees of the studied cultivars and breeding clones to find common ancestors. Finally, the pedigree relationships and verticillium resistance ratings, where available, were depicted in the form of an annotated pedigree map, which was constructed using Pedimap[™] software (Wageningen UR – Plant Breeding). The development of the BIMS crop reference data set and current Pedimap resource are products of the USDA-NIFA-SCRI RosBREED and EU-FruitBreedomics (www.fruitbreedomics.com) projects.

Results

The results of our verticillium inoculation response screenings are summarized for the diploid and polyploid genotypes, respectively, in Tables 1 and 2. In the tables, the accessions are ordered by species, subspecies, and mean disease rating, where the latter value is the mean of the individual plant scores for the accession in question. On the basis of their mean disease ratings, the assayed genotypes were then classified as VR, MR, I, MS, or VS, and our classifications of octoploid germplasm were integrated where appropriate into Table 3.3 for comparison with those of previous investigators.

Some accessions that displayed relatively high levels of resistance or susceptibility were screened more than once, with the aim of confirming their suitability for use as parents in resistant × susceptible crosses. In early trials, diploid *Fragaria vesca* accession TMD2 was identified as moderately resistant and BC30 was identified as very susceptible, while among octoploid accessions *Fragaria virginiana* CFRA1699 was identified as very resistant and CFRA1455 and CFRA1408 were identified as very susceptible. These five accessions were used as resistant and susceptible controls, respectively, in subsequent trials, and therefore are represented by larger numbers of inoculated plants as indicated in the "N" column in Table 3.2. Importantly, these comparator accessions displayed consistent resistant or susceptible responses under both greenhouse and growth room conditions.

At the diploid level, the mean ratings of the 15 *F. vesca* accessions ranged from 1.5 to 3.0 (Table 3.1). The most resistant *F. vesca* accessions, all with mean ratings of 1.5, were one accession from British Columbia (BC5) and two from Mendocino County, California (U2A and TMD2); while the most susceptible, all with mean ratings of 2.9 to 3.0, were three accessions from British

Columbia (BC3, BC30, and GS1J), two from California (DN2A and HP3A) and one from New Hampshire ('Pawtuckaway'). The three representatives of *F. vesca* subsp. *americana* (WC6, WC8, and 'Pawtuckaway') all had mean ratings in the moderately-to-very susceptible range (2.6 to 3.0), while both resistance and susceptibility was seen among the *F. vesca* accessions from California and among those from British Columbia. The other diploid accessions included three species (*F. bucharica, F. iinumae*, and *F. viridis*) and one interspecific hybrid (CFRA364) that were each represented by a single accession and had mean ratings in the very-to-moderately resistant range of 1.0 to 1.7 (Table 3.1). Among the four accessions of *F. nipponica*, mean ratings ranged from 1.3 (very resistant) to 2.0 (intermediate).

Among the wild polyploid accessions, the mean ratings of octoploids *F. chiloensis* and *F. virginiana* ranged from 1.6 to 3.0 and 1.2 to 3.0, respectively (Table 3.2). The only wild octoploid accession categorized as "very resistant" was *F. virginiana* subsp. *virginiana* CFRA1699, while three and four accessions of *F. chiloensis* and *F. virginiana*, respectively, were categorized as "very susceptible". The single representative of decaploid *F. cascadensis* (CFRA110) was also categorized as very susceptible (mean rating 3.0). Among the ten cultigens of octoploid *F. ×ananassa*, mean ratings ranged from 1.0 to 3.0 (Table 3.2). 'Tristar' (1.0) and breeding clone M903 (1.3) were categorized as very resistant, while 'Mira', 'Evangeline', 'Laurel', and breeding clone K05-9 were categorized as very susceptible. We examined the ancestries of rated cultigens with the aid of the constructed pedigree (Figure 3.2), with the exception of very susceptible rated breeding clone K05-9 which, as an open-pollinated selection from an unknown Driscoll variety has unknown parentage and so could not be integrated into the

pedigree. Previous verticillium resistance ratings were unavailable for both parents of 'Tristar', 'Evangeline' and 'M903', while ratings for only one parent each were available for 'Wendy', and 'Annapolis'. Among the four cultigens for which both parents had available ratings, the very susceptible 'Mira' had very susceptible parents 'Scott' and 'Honeoye'; the very susceptible 'Laurel' had intermediate parents 'Allstar' and 'Cavendish'; the very susceptible 'Sparkle' had as parents intermediate 'Fairfax' and very resistant 'Aberdeen'; and the intermediate 'Cavendish' had as parents very susceptible 'Glooscap' and intermediate 'Annapolis'. Similarly, in some instances where all ratings came from literature sources, very resistant 'Etna' had very susceptible parents 'Belrubi' and 'Marlate'; moderately resistant 'Temple' had as parents very resistant 'Aberdeen' and intermediate 'Fairfax'; and very susceptible 'Bounty' had as parents very susceptible 'Jerseybelle' and very resistant 'Senga Sengana' (Figure 3.2).

Based upon the foregoing results, we identified promising intra-specific crossing combinations between moderately (MR) or very resistant (VR) and very susceptible (VS) parents, at the diploid (F. vesca) and octoploid (F. virginiana) levels, respectively: diploid TMD2 (MR) \times BC30 (VS); octoploid CFRA1408 (VS) \times CFRA1699 (VR), and octoploid CFRA1455 (MS) \times CFRA1699 (VR). We have performed the indicated crosses and generated F1 hybrid progeny. The results from an initial screening (to be reported elsewhere) are indicative of segregation for resistance/susceptibility in the F1 progeny of each cross, suggesting that one or both parents in each cross are heterozygous for genetic determinants of resistance.

In our literature survey, ratings were found for 67 cultigens in studies performed during the period of 1955-2013 (Table 3.2). There were 33 instances wherein a given cultivar was rated by two or more studies. The present study added ratings for five cultivars that had not been previously evaluated for verticillium resistance and complemented ratings for four cultivars that had been previously studied. The prior investigations employed varying terminologies for qualitative classification of resistance/susceptibility. The terminologies we have used in summarizing ratings reports from these prior studies in Table 3.3 are those of the respective investigators and/or conversions or extrapolations of prior ratings to those categories used in the present study.

^zScores (VS = Very Susceptible, MS = Moderately Susceptible, I = Intermediate, MR = Moderately Resistant, VR = Very Resistant, T = Tolerant, U = Unknown). Note: the term "tolerant" has been used in differing ways by various authors. The superscript following the qualitative rating corresponds to the superscript preceding the cited literature in the same row.

Discussion

Phenotypic assessment provides guidance to the collection and archiving of plant germplasm, and generates knowledge resources of value to breeders and geneticists interested in understanding and manipulating specific traits. The trait of interest to the present study is resistance/susceptibility to the destructive fungal disease, verticillium wilt. This report advances knowledge about the occurrence and inheritance of wilt resistance and susceptibility in wild and cultivated strawberry germplasm in the following ways. First, we present new disease resistance/susceptibility data for 50 Fragaria germplasm accessions representing three levels of ploidy. We also summarize and synthesize pre-existing knowledge and resistance ratings from diverse publicly available but in some cases obscure sources. Finally, we define and informatively display pedigree relationships among a selected group of resistant and susceptible strawberry cultigens, thereby graphically documenting both the extent of, and the gaps in, present knowledge about verticillium susceptibility in a coherent assemblage of important strawberry germplasm.

In the performance of our verticillium wilt resistance/susceptibility screenings, we employed a five point categorical rating scale that, on a single plant basis, ranged from "healthy" to "dead". We also employed a parallel scale for classifying genotypes based upon their mean ratings, ranging from very resistant (VR) to very susceptible (VS).

In our screenings of diploid germplasm, broad variability in disease responses was observed among the sixteen *Fragaria vesca* accessions, ranging from moderately resistant to very susceptible. The evident biodiversity within *F. vesca* provides an attractive opportunity for association genetics studies within this species, which among strawberry species is currently

unique in having an available reference genome sequence (Shulaev et al. 2011). Among the other diploids tested, all ratings fell within the intermediate to very resistant range. As in our own study, (Olbricht et al. 2009) detected variation for verticillium wilt resistance/susceptibility both within and between *Fragaria* species. Among ten diploid species tested by (Olbricht et al. 2009), susceptibility was reported in at least one representative each of five diploid species, including the only identified *F. vesca* accession included in their study. Perhaps importantly, consistent "tolerance," where the pathogen was internally present but the host plant was asymptomatic, was found only in *F. iinumae* (Olbricht et al. 2009), while in our own study the only tested representative of *F. iinumae* ranked among the most resistant of our diploid accessions (Table 3.1). Like *F. vesca, F. iinumae* is of particular interest because of its status as an ancestral subgenome donor to the octoploid species (Folta et al. 2006).

At the octoploid level, the opportunity to identify sources of resistance for exploitation in breeding programs is of particular interest. Although a panel of octoploid cultivars was included in our study, as later discussed, we emphasized the analysis of wild octoploid germplasm belonging to the USDA supercore collection (Hancock et al. 2001). Upon incorporation into the GRIN database, our results will add further value to the supercore collection by expanding the knowledge resources associated with its members.

Among the wild polyploids, high levels of susceptibility were found in at least one representative of each of the two octoploid species, *F. chiloensis* and *F. virginiana*, and in the only representative of decaploid *F. cascadensis*. Moderate to elevated levels of resistance also occurred in each of the wild octoploid species; however, of the wild octoploids only *F. virginiana* subsp. *virginiana* accession Montreal River 10 (CFRA1699) was rated as very resistant. CFRA1699 has also been determined to possess a number of favorable horticultural

traits, including resistance to common foliar diseases, and has been used extensively in the *F*. \times *ananassa* reconstruction project (Hancock et al. 2001, Hancock et al. 2010, Stegmeir et al. 2010). Another accession, LH50-4 (CFRA1697), used extensively in the *F*. \times *ananassa* reconstruction project due to its day-neutrality trait, cold hardiness, fruit color, and resistance to root knot nematode (Hancock et al. 2001, Hancock et al. 2010, Stegmeir et al. 2010), was rated as very susceptible to verticillium wilt in our study.

Several studies of verticillium resistance in wild octoploid *Fragaria* germplasm have appeared, mostly in pre-1970's literature (McKeen et al. 1955, Wilhelm 1955, Wilhelm 1955, vanAdrichem et al. 1958, Bringhurst et al. 1966). These early reports document, with varying degrees of precision, the sites of origin (collection) of the studied materials, and thus point subsequent investigators to potentially valuable sites for future collections.

In a multi-inoculation greenhouse trial (Wilhelm 1955), no resistance was found among two *F. virginiana* clones and 39 seedlings, but the source or origin of the *F. virginiana* accessions was not provided. In contrast, Varney et al. (Varney et al. 1959) found the so called "Sheldon" clone of *F. virginiana* to be very resistant. In a multi-inoculation greenhouse trial, Newton and van Adrichem (Newton et al. 1958) found no resistance in 49 evaluated Ontario *F. virginiana* seedlings, while we rated an Ontario accession, CFRA1699, as very resistant.

Of the two ancestral octoploid species, great attention has been given to the occurrence and transmission of verticillium resistance in *F. chiloensis*. Newton and van Adrichem (Newton et al. 1958) found 8 resistant out of 40 evaluated Oregon coast *F. chiloensis* seedlings. (Wilhelm 1955) found no resistance in *F. chiloensis* from Ambato, Peru. However, we found Peruvian *F. chiloensis* CFRA372, an accession used in *the F. ×ananassa* reconstruction project for its fruit qualities and resistance to root lesion nematodes (Hancock et al. 2010), to be moderately resistant to verticillium wilt. Additional *F. chiloensis* accessions CFRA24, CFRA1088, CFRA1691, and CFRA34 are also involved in the *F.* ×*ananassa* reconstruction project (Hancock et al. 2010), and we found these accessions moderately to very susceptible to verticillium wilt. In a field and greenhouse study of 1009 *F. chiloensis* clones from 14 sites along the California coast from Santa Maria to just north of San Francisco, Bringhurst et al. (1966) found that where multiple clones were sampled per site, a range of resistance and susceptibility was detected within sites, suggesting the possibility of segregation for resistance/susceptibility among seedling-derived plants within sites. For instance, from their Bodega Bay site, Bringhurst et al. (1966) found one resistant *F. chiloensis* clone and two susceptible clones, in comparison to 12 resistant clones previously reported by Wilhelm (1955).

Bringhurst et al. (1966) found the entire range of resistance to susceptibility among six clones from Pigeon Point, the collection site of FRA357, which was categorized as moderately resistant in our study. Similarly, Bringhurst et al. (1966) found intermediate to extreme susceptibility at the Scotts Creek site, the collection site for CFRA1692, which was used extensively in horticultural trait evaluations and in the *F.* ×*ananassa* reconstruction project (Hancock et al. 2010, Stegmeir et al. 2010), but for which we do not have verticillium wilt resistance data. We found *F. chiloensis* accessions CFRA34 (Redwoods Creek Park) and CFRA1691 (Jessie M. Honeyman Memorial State Park, Oregon) both to be very susceptible to verticillium wilt; however as the findings of Bringhurst et al. (1966) suggest, a more in-depth collection from these sites might recover resistant individuals as well. Future collections including numerous clones for screening would be prudent, as was done by (Bringhurst et al. 1966), for there is apparent diversity for resistance within individual sites.

Upon finding that one *F. chiloensis* genotype was highly resistant to verticillium wilt, (Maas et al. 1989) recommended that efforts should be increased to evaluate *F. chiloensis* clones as a potential source of resistance for use in strawberry breeding. Previously, (vanAdrichem et al. 1958) suggested that *F. chiloensis* might have been the introgressive source of verticillium resistance already employed in some breeding programs. Screenings of progenies derived from cultivar \times *F. chiloensis* crosses (Olbricht et al. 2006), including crosses involving susceptible 'Elsanta', identified two wild accessions, *F. chiloensis* ssp. *lucida* E2/1 (California) and *F. chiloensis* ssp. *pacifica* 'Yaquina' (Oregon) as potential sources of resistance. In contrast, when 'Elsanta' was crossed with the *F. chiloensis* cultivar 'Culture' (Chile), over one third of the progeny plants succumbed to wilt.

For about half of the cultigens that we assayed in the present study, our literature survey uncovered results of prior wilt resistance testing (Table 3.2). Although the prior studies varied in relation to environment (field or greenhouse) and to methodological aspects such as inoculation techniques, *Verticillium* isolates, and inoculum concentrations, our results from specific cultivars were generally consistent with those previously reported (Table 3.2). For instance, we rated 'Tristar' as very resistant, while it has previously been rated as very resistant, tolerant, and moderately resistant (See Table 3.3 and citations therein). We rated 'Annapolis' as intermediate, and it was also rated as such by (Maas et al. 1989). We rated 'Cavendish' as intermediate, while it has elsewhere been rated as moderately resistant (Jamieson et al. 1991). Thus, we have reason to be confident that our results provide an accurate and useful description of the tested germplasm.

Upon gathering information about ancestors of cultigens employed in the present study, some disagreements among prior studies were evident in the literature. Different ratings were found for 'Howard17' (Table 3.3), which is suspected of having two different clones (Bringhurst et al. 1961). Disagreements among studies may also stem from differing experimental conditions. Resistance to different sources of *Verticillium dahliae* isolates resulted in different resistance ratings (Maas et al. 1989, Gordon et al. 2006), and susceptibility to wilt was synergistically increased when coincident with infection by the nematode *Pratylenchus penetrans* (Muller 1973, Potter et al. 1991).

The pedigree diagram (Figure 3.2) depicts information available to us about the ancestries of nine of the ten strawberry cultigens tested, tracing back as many as 12 generations from the most recent 'Wendy' release. All but two of these ('Sparkle' and 'Tristar') are products of the Nova Scotia breeding program. Notably, verticillium wilt resistance ratings are presently available for only 67 out of the 130 cultigens in the pedigree. Of the 63 cultigens with no available ratings, only 12 are named cultivars. The available ratings span a spectrum from very resistant to very susceptible; suggesting that considerable insight into the genetic basis of verticillium wilt resistance/susceptibility could be distilled from the described germplasm, provided that the missing resistance ratings could be filled in.

We observed that resistance can appear in progeny (e. g. 'Etna') of a cross between two susceptible parents (e.g. 'Belrubi' and 'Marlate'). Thus, the possible existence of dominant genetic factors for susceptibility must be considered, as must the possibility that resistance could be "introduced" into a susceptible breeding line simply by providing opportunity for resistance to emerge through progeny segregation, even with self-pollination of susceptible types (vanAdrichem et al. 1958).

We anticipate that useful insights will be gained through examination of breeding pedigrees, such as that depicted in Figure 3.2. However, the power of the pedigree approach can
be maximized only when phenotype information is available for all pedigree members. 'Tristar' is described in its release note as resistant to verticillium wilt, leaf blight, powdery mildew, and red stele root rot, as well as tolerant to leaf blight (Draper et al. 1981). We confirmed its wilt resistance in the present study. Although, the day-neutrality trait of 'Tristar' is attributed to introgression from *F. virginiana* ssp. *glauca* via CA65.65-601 (Draper et al. 1981), the source(s) of wilt resistance is/are unclear, as there were multiple opportunities for either resistance or susceptibility to be transmitted from cultigens in its pedigree, both with and without known verticillium wilt resistance (Figure 3.2). Overall, the high level of progeny segregation and the lack of any consistent pattern of resistance transmission in the pedigree suggest high levels of heterozygosity. It is likely that verticillium wilt resistance is a polygenic trait in the cultivated strawberry. Thus, an abundance of opportunities exist to breed for increased resistance.

CONCLUSIONS

Recurrent themes unite the research reported in the foregoing chapters. One of these is the abundance of diversity available in Fragaria germplasm, and the development of new germplasm resources for genetic research and breeding. A second theme is the validation and application of high-throughput genotyping platforms. The Axiom IStraw90® strawberry SNP array was validated as an effective tool for genotyping at both the diploid and octoploid levels in strawberry. Genotyping-by-Sequencing was shown to be a valuable and complementary marker technology, enabling the identification of markers in genomic regions that were underrepresented on the IStraw90 Array. The abundant potential for gain from selection with respect to many traits, including fruit and ornamental qualities and diseases resistance, was demonstrated in octoploid germplasm, providing the basis for expansion of breeding activities aimed at developing locally adapted varieties at the New Hampshire Agricultural Experiment Station. As tangible research products, the first linkage maps of the ancestral diploid Fragaria iinumae were constructed, markers associated with a trait of horticultural interest - NW flower color - were identified, and population development was initiated toward the goal of marker-assisted breeding for verticillium resistance. Finally, several attractive directions for further research progress were defined. A set of candidate genes on chromosome five were identified in relation to the NW flower color trait. The trait instability with respect to NW flower color deserves further exploration and explanation. Potential genomic rearrangements between diploids F. iinumae and F. vesca warrant further investigation.

Looking ahead, the *F. iinumae* linkage map, as described in Chapter I, will be used in an effort to generate a de novo assembly of the *F. iinumae* genome to provide a second *Fragaria* reference genome. The linkage map and reference sequence are anticipated to be used in the future for various genetic studies, including identification of subgenomes in octoploid strawberry.

As described in Chapter II, a Closed Pedigree Set of four generations segregating for NW versus W flower color and for hues of NW was developed from previously identified octoploid germplasm (Mahoney 2007, Mahoney et al. 2009) as sources of unique and favorable fruit pelargonidin and cyanidin contents, or of NW flower color. Selections with the sought after red flower color were achieved in the Closed Pedigree Set, and dominance of NW over W was determined. The upper end of the range of anthocyanin floral content of the Closed Pedigree Set exceeded that of the NW founder, indicating that the white-flowered founders contributed determinants of floral anthocyanin content and hue. Factors impacting selection against the NW flower trait in the initial generations and then favoring the NW flower trait are evident. Using a pedigree-based approach, 35 Array SNP markers co-segregating with flower color were identified: 28 of which are syntenous with PC5 of FvH4, and span a homoeologue of chromosome 5. Potential candidate genes related to anthocyanin biosynthesis and located on PC5 of FvH4 were identified, the most intriguing being two regulatory genes, FaMYB1 and JAF13. In the second phase of the program, and taking advantage of selections in Phase 1, select members were crossed with commercial cultivars to develop hybrids with attractive flowers and sizable and delicious fruit. Ten members of the Phase 2 LM49 family were selected by Pleasant View Gardens for evaluation.

In Chapter III, the final chapter, using a pedigree based approach and phenotypic data on verticillium wilt disease resistance, potential sources of disease resistance and susceptibility were identified and parents were selected for crosses of resistant \times susceptibility for the next phase of genotyping on the Array, for identification of QTLs for resistance.

My post-doctoral research plans are to continue breeding strawberry, including both ornamental and production varieties and to advance marker-assisted breeding in strawberry, utilizing the Array, a break-through technology. An additional 104 members of the Closed Pedigree Set progeny have now been genotyped on the Array, and the data await analysis. A selected progeny individual LMJ6 derived from the three founders has been crossed with two locally popular cultivars, for the purpose of introgressing flower color, hue, and fruit pigment genes into a cultivated strawberry with acceptable fruit size and quality.

APPENDICES

APPENDIX A

ARRAY AND GBS MARKER DATA FOR THE 21 F2D MAP

TABLE A: F. iinumae 21F2D mapped markers and F. vesca reference information. In the table heading, the Marker ID for the Array are 8 digits long and begin with 89, and the GBS markers are the remaining markers. The Type indicates the type of marker on the Array or is simply referred to as GBS for the GBS data. The quality ratings of the genotyping for the Array markers are provided in the Class column, and for the mapped markers included PHR (poly high resolution), CRBT (call rate below threshold), Other, and NoCls (the mSnps, where qualities were not categorized). The SNP nucleotides are provided for the Array markers in the Allele columns. The SNP nucleotides are also provided in the Query sequence column in [brackets] for the Array and as the degenerate code for the GBS markers. The location of the markers on the F. vesca "Hawaii 4" H4_v1.1 reference map, version pseudochromosome (PC); and position in base-pair designation (Start) and for GBS data only (Finish). Referring to the PC column: for the GBS markers that could not be located on the mapped FvH4 version 1.1 pseudochromosomes, thirteen were located on unmapped FvH4 v1.1 PC0; one marker (3^{z}) could only be located on F. vesca pseudo- chromosome v.1.0 PC3; twenty-three markers could only be found on F. vesca reference v1.1 scaffold database (SCF^y refers to scf0513160 and SCF^x refers to scf051358b); and forty markers could not be located in any of the FvH4 databases, and these are designated as 'No good hits' abbreviated 'NGH'.

Table A: Mapped markers of *F. iinumae* 21F2D map and comparison to *F. vesca* reference physical map

APPENDIX B

21F2D MAP POSITIONS AND SEGREGRATION DATA

Table B: *F. iinumae* **F1D** segregation data for the 21F2D map. The *F. iinumae* map includes Array and GBS markers for the 21 F2Ds. Each bin comprises markers that co-segregate without recombination. The locus column includes the bin name followed by a '–' and the number of markers in the corresponding bin. The map positions are given in centi-Morgans, cM. The parents genotypes 0, 1, 2 are the Affymetrix genotype calls for AA, AB, BB respectively.

The F2Ds genotypic calls are in JoinMap code for an F2 mapping population. The cells are colored as follows: the a's are yellow, the b's are white, the h's are green, and the missing data are white.

Table B: F. iinumae F1D segregation data for the 21F2D map.
APPENDIX C

F. iinumae 85F2D MAP POSITIONS AND SEGREGRATION DATA

Table C: *F .iinumae* **F1D segregation data for the 85F2D map.** This *F. iinumae* map includes only GBS markers for the 85 F2Ds. Each bin comprises markers that co-segregate without recombination. The locus column includes the bin name followed by a dash '–' and the number of markers in the corresponding bin. The map positions are given in centi-Morgans, cM. The parents genotypes 0, 1, 2 are the Affymetrix genotype calls for AA, AB, BB respectively.

The F2Ds genotypic calls are in JoinMap code for an F2 mapping population. The cells are colored as follows: the a's are yellow, the b's are white, the h's are green, and the missing data are white.
